Understanding Embedded - FPGAs (Field Programmable Gate Array)

Embedded - FPGAs, or Field Programmable Gate Arrays, are advanced integrated circuits that offer unparalleled flexibility and performance for digital systems. Unlike traditional fixed-function logic devices, FPGAs can be programmed and reprogrammed to execute a wide array of logical operations, enabling customized functionality tailored to specific applications. This reprogrammability allows developers to iterate designs quickly and implement complex functions without the need for custom hardware.

Applications of Embedded - FPGAs

The versatility of Embedded - FPGAs makes them indispensable in numerous fields. In telecommunications.

Details	
Product Status	Obsolete
Number of LABs/CLBs	3584
Number of Logic Elements/Cells	-
Total RAM Bits	1769472
Number of I/O	720
Number of Gates	3000000
Voltage - Supply	1.425V ~ 1.575V
Mounting Type	Surface Mount
Operating Temperature	-40°C ~ 100°C (TJ)
Package / Case	1152-BBGA, FCBGA
Supplier Device Package	1152-FCBGA (35x35)

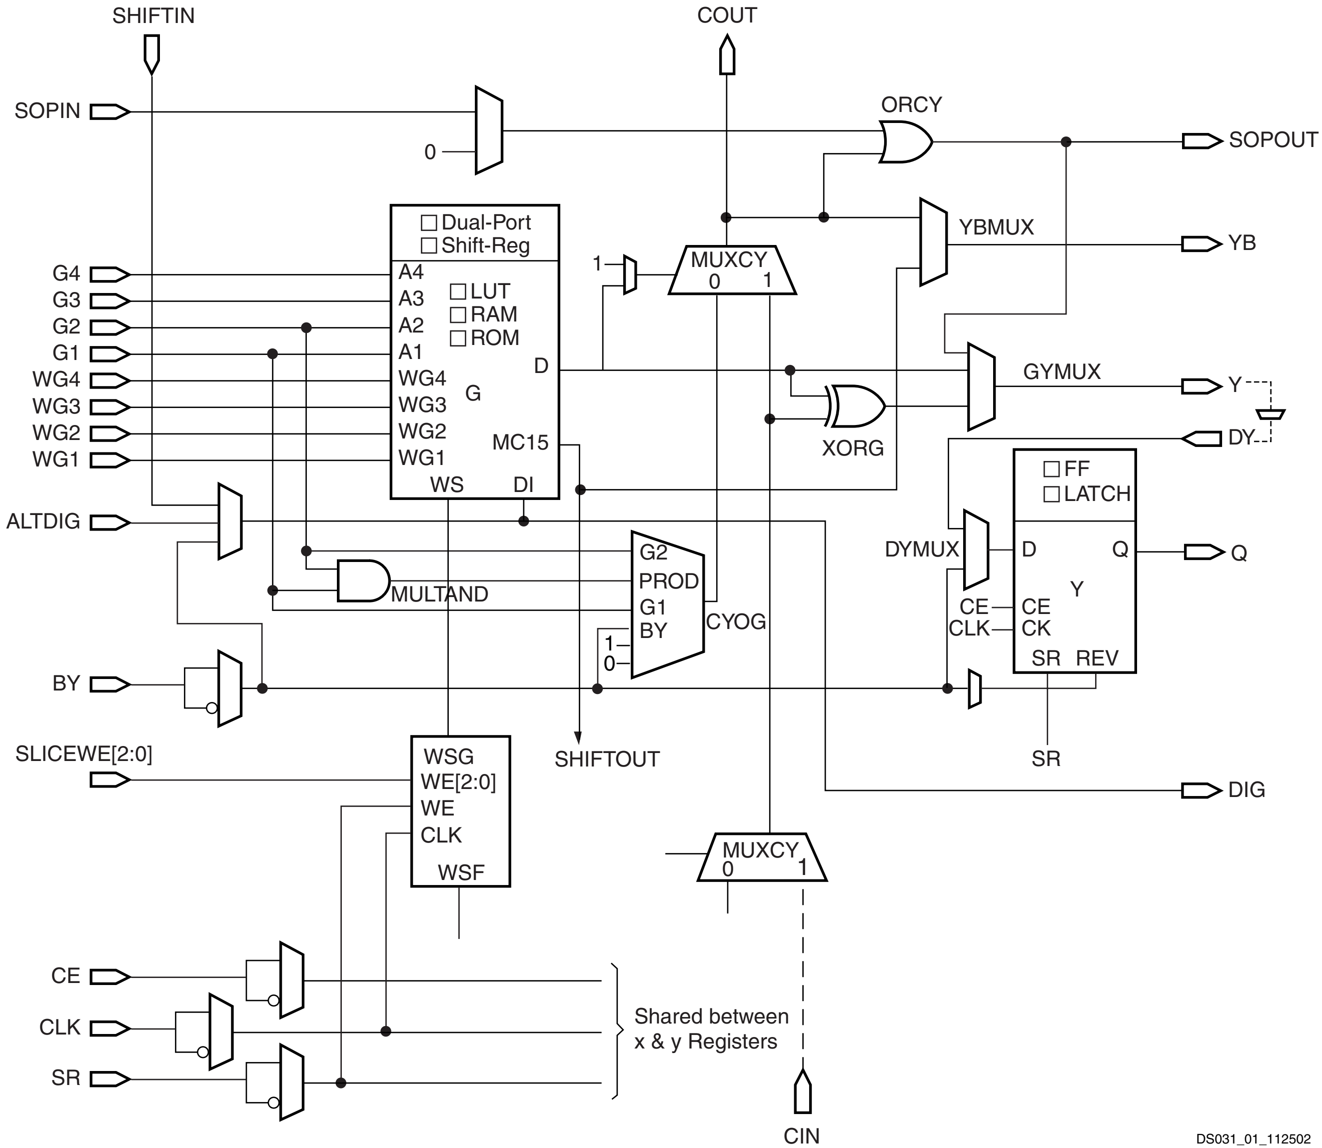

Figure 16: **Virtex-II Slice (Top Half)**

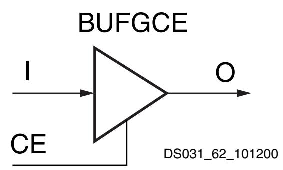

Figure 42: **Virtex-II BUFGCE Function**

If the CE input is inactive (Low) prior to the incoming rising clock edge, the following clock pulse does not pass through the clock buffer, and the output stays Low. Any level change of CE during the incoming clock High time has no effect. CE must not change during a short setup window just prior to the rising clock edge on the BUFGCE input I. Violating this setup time requirement can result in an undefined runt pulse output.

BUFGMUX

BUFGMUX can switch between two unrelated, even asynchronous clocks. Basically, a Low on S selects the I0 input, a High on S selects the I1 input. Switching from one clock to the other is done in such a way that the output High and Low time is never shorter than the shortest High or Low time of either input clock. As long as the presently selected clock is High, any level change of S has no effect .

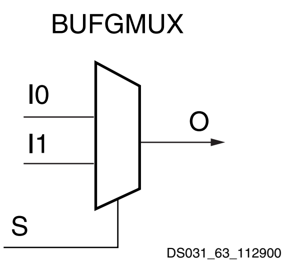

Figure 43: **Virtex-II BUFGMUX Function**

If the presently selected clock is Low while S changes, or if it goes Low after S has changed, the output is kept Low until the other ("to-be-selected") clock has made a transition from High to Low. At that instant, the new clock starts driving the output.

The two clock inputs can be asynchronous with regard to each other, and the S input can change at any time, except for a short setup time prior to the rising edge of the presently selected clock (I0 or I1). Violating this setup time requirement can result in an undefined runt pulse output.

All Virtex-II devices have 16 global clock multiplexer buffers.

Figure 44 shows a switchover from I0 to I1.

- The current clock is CLK0.
- S is activated High.
- If CLK0 is currently High, the multiplexer waits for CLK0 to go Low.
- Once CLK0 is Low, the multiplexer output stays Low until CLK1 transitions High to Low.
- When CLK1 transitions from High to Low, the output switches to CLK1.
- No glitches or short pulses can appear on the output.

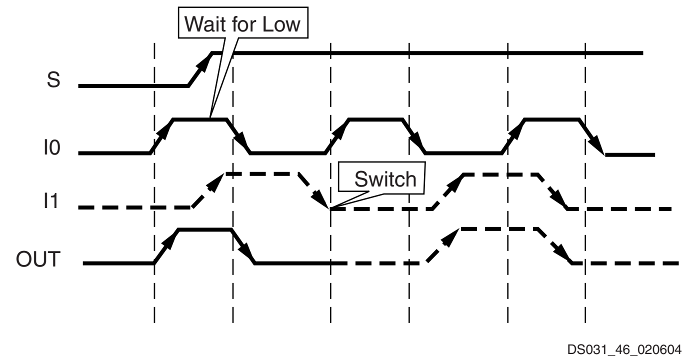

Figure 44: **Clock Multiplexer Waveform Diagram**

Local Clocking

In addition to global clocks, there are local clock resources in the Virtex-II devices. There are more than 72 local clocks in the Virtex-II family. These resources can be used for many different applications, including but not limited to memory interfaces. For example, even using only the left and right I/O banks, Virtex-II FPGAs can support up to 50 local clocks for DDR SDRAM. These interfaces can operate beyond 200 MHz on Virtex-II devices.

Digital Clock Manager (DCM)

The Virtex-II DCM offers a wide range of powerful clock management features.

- **Clock De-skew**: The DCM generates new system clocks (either internally or externally to the FPGA), which are phase-aligned to the input clock, thus eliminating clock distribution delays.
- **Frequency Synthesis**: The DCM generates a wide range of output clock frequencies, performing very flexible clock multiplication and division.
- **Phase Shifting**: The DCM provides both coarse phase shifting and fine-grained phase shifting with dynamic phase shift control.

The DCM utilizes fully digital delay lines allowing robust high-precision control of clock phase and frequency. It also utilizes fully digital feedback systems, operating dynamically to compensate for temperature and voltage variations during operation.

Up to four of the nine DCM clock outputs can drive inputs to global clock buffers or global clock multiplexer buffers simultaneously (see Figure 45). All DCM clock outputs can simultaneously drive general routing resources, including routes to output buffers.

Notes:
1. V_{OL} and V_{OH} for lower drive currents are sample tested. The DONE pin is always LVTTL 12 mA.
2. Tested according to the relevant specifications.
3. LVTTL and LVCMOS inputs have approximately 100 mV of hysteresis.

Virtex-II Performance Characteristics

This section provides the performance characteristics of some common functions and designs implemented in Virtex-II devices. The numbers reported here are worst-case values; they have all been fully characterized. Note that these values are subject to the same guidelines as Virtex-II Switching Characteristics, page 9 (speed files).

Table 11 provides pin-to-pin values (in nanoseconds) including IOB delays; that is, delay through the device from input pin to output pin. In the case of multiple inputs and outputs, the worst delay is reported.

BG575/BGG575 Standard BGA Package

As shown in Table 9, XC2V1000, XC2V1500, and XC2V2000 Virtex-II devices are available in the BG575/BGG575 BGA package. Pins in the XC2V1000, XC2V1500, and XC2V2000 devices are the same, except for the pin differences in the XC2V1000 and XC2V1500 devices shown in the No Connect columns. Following this table are the BG575/BGG575 Standard BGA Package Specifications (1.27mm pitch).
