What is "Embedded - Microcontrollers"?

"Embedded - Microcontrollers" refer to small, integrated circuits designed to perform specific tasks within larger systems. These microcontrollers are essentially compact computers on a single chip, containing a processor core, memory, and programmable input/output peripherals. They are called "embedded" because they are embedded within electronic devices to control various functions, rather than serving as standalone computers. Microcontrollers are crucial in modern electronics, providing the intelligence and control needed for a wide range of applications.

2.2.1 Package Pin Summary

The following general scheme is used to describe each pin:

Table 8 Package Pin Mapping Description

Function	Package A	Package B	...	Pad Type	Notes
Name	N	Ax	...	A2	

The table is sorted by the “Function” column, starting with the regular Port pins (Px.y), followed by the dedicated pins (i.e. PORST) and supply pins.

The following columns, titled with the supported package variants, lists the package pin number to which the respective function is mapped in that package.

The “Pad Type” indicates the employed pad type (A1, A1+, A2, special=special pad, In=input pad, AN/DIG_IN=analog and digital input, Power=power supply). Details about the pad properties are defined in the Electrical Parameters.

In the “Notes”, special information to the respective pin/function is given, i.e. deviations from the default configuration after reset. Per default the regular Port pins are configured as direct input with no internal pull device active.

3.1.3 Pin Reliability in Overload

When receiving signals from higher voltage devices, low-voltage devices experience overload currents and voltages that go beyond their own IO power supplies specification.

Table 13 defines overload conditions that will not cause any negative reliability impact if all the following conditions are met:

- full operation life-time is not exceeded
- **Operating Conditions** are met for
  - pad supply levels (V_{DDP} or V_{DDA})
  - temperature

If a pin current is outside of the **Operating Conditions** but within the overload conditions, then the parameters of this pin as stated in the Operating Conditions can no longer be guaranteed. Operation is still possible in most cases but with relaxed parameters.

Note: An overload condition on one or more pins does not require a reset.

Note: A series resistor at the pin to limit the current to the maximum permitted overload current is sufficient to handle failure situations like short to battery.

3.2 DC Parameters

3.2.1 Input/Output Pins

The digital input stage of the shared analog/digital input pins is identical to the input stage of the standard digital input/output pins.
The Pull-up on the $\overline{\text{PORST}}$ pin is identical to the Pull-up on the standard digital input/output pins.

Note: These parameters are not subject to production test, but verified by design and/or characterization.

Table 19 Standard Pad Parameters

		–		10	µA	2) $V_{IN} \leq 0.36 \times V_{DDP}$
Pull-Up current	$\lvert I_{PUH}\rvert$ CC	–		10	µA	2) $V_{IN} \geq 0.6 \times V_{DDP}$
		100		–	µA	1) $V_{IN} \leq 0.36 \times V_{DDP}$

$\overline{\text{PORST}}$ pull-down current	$\lvert I_{PPD}\rvert$ CC	13		–	mA	V_{IN} = 1.0 V

1) Current required to override the pull device with the opposite logic level (“force current”). With active pull device, at load currents between force and keep current the input state is undefined.

2) Load current at which the pull device still maintains the valid logic level (“keep current”). With active pull device, at load currents between force and keep current the input state is undefined.

3) Hysteresis is implemented to avoid metastable states and switching due to internal ground bounce. It can not be guaranteed that it suppresses switching due to external system noise.

Input leakage current at RTC_XTAL1	I_{ILX1} CC	-100	–	100	nA	Oscillator power down 0 V ≤ V_{IX} ≤ V_{BAT}

1) t_{OSCS} is defined from the moment the oscillator is enabled by the user with SCU_OSCULCTRL.MODE until the oscillations reach an amplitude at RTC_XTAL1 of 400 mV.

2) The external oscillator circuitry must be optimized by the customer and checked for negative resistance and amplitude as recommended and specified by crystal suppliers.

3) For a reliable start of the oscillation in crystal mode it is required that $V_{BAT} \geq 3.0$ V. A running oscillation is maintained across the full V_{BAT} voltage range.

4) If the shaper unit is enabled and not bypassed.

5) If the shaper unit is bypassed, dedicated DC-thresholds have to be met.

6) Hysteresis is implemented to avoid metastable states and switching due to internal ground bounce. It can not be guaranteed that it suppresses switching due to external system noise.

3.3.2 Power-Up and Supply Monitoring

$\overline{\text{PORST}}$ is always asserted when V_{DDP} and/or V_{DDC} violate the respective thresholds.

Note: These parameters are not subject to production test, but verified by design and/or characterization.

		Min.	Typ.	Max.

1) Minimum threshold for reset assertion.

2) Maximum threshold for reset deassertion.
3) The V_{DDP} monitoring has a typical hysteresis of V_{PORHYS} = 180 mV.
4) If t_{PR} is not met, low spikes on $\overline{PORST}$ may be seen during start up (e.g. reset pulses generated by the supply monitoring due to a slow ramping V_{DDP}).

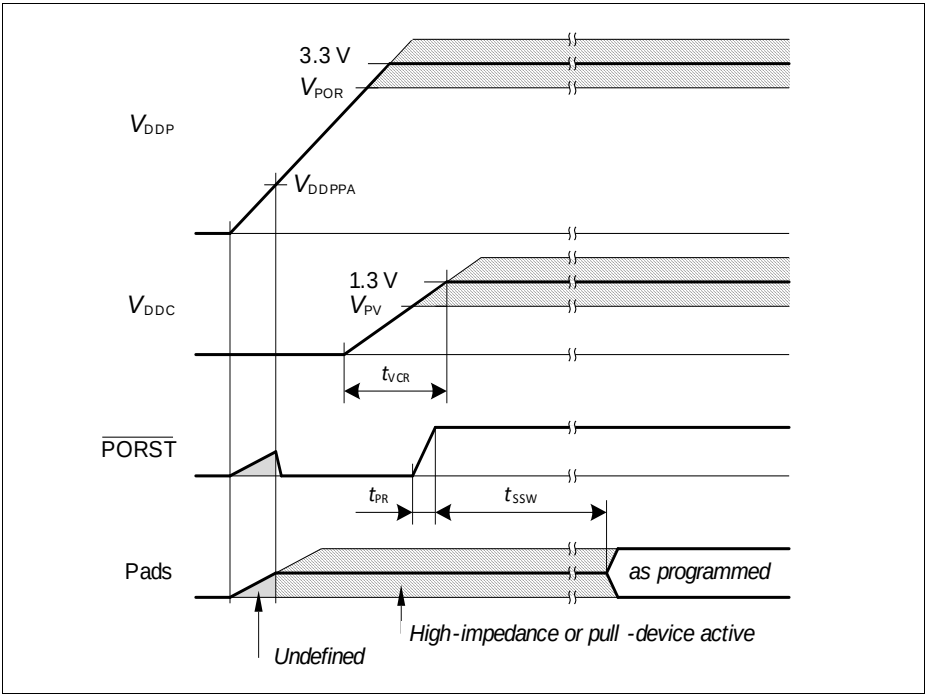

Figure 26 Power-Up Behavior

3.3.3 Power Sequencing

While starting up and shutting down as well as when switching power modes of the system it is important to limit the current load steps. A typical cause for such load steps is changing the CPU frequency f_{CPU}. Load steps exceeding the below defined values may cause a power on reset triggered by the supply monitor.

Note: These parameters are not subject to production test, but verified by design and/or characterization.

3.3.5 Internal Clock Source Characteristics

Note: These parameters are not subject to production test, but verified by design and/or characterization.

Fast Internal Clock Source

Table 37 Fast Internal Clock Parameters

Parameter	Symbol	Values			Unit	Note / Test Condition
		Min.	Typ.	Max.		
Nominal frequency	f_{OFINC} CC	–	36.5	–	MHz	not calibrated
		–	24	–	MHz	calibrated
Accuracy	Δf_{OFI} CC	-0.5	–	0.5	%	automatic calibration[1)2)]
		-15	–	15	%	factory calibration, V_{DDP} = 3.3 V
		-25	–	25	%	no calibration, V_{DDP} = 3.3 V
		-7	–	7	%	Variation over voltage range[3)] 3.13 V ≤ V_{DDP} ≤ 3.63 V
Start-up time	t_{OFIS} CC	–	50	–	µs	

1) Error in addition to the accuracy of the reference clock.

2) Automatic calibration compensates variations of the temperature and in the V_{DDP} supply voltage.

3) Deviations from the nominal V_{DDP} voltage induce an additional error to the uncalibrated and/or factory calibrated oscillator frequency.

No clock delay:

(7)

$$t_{ODLY\_H} + t_{DATA\_DELAY} + t_{TAP\_DELAY} + t_{ISU} < t_{WL}$$

With clock delay:

(8)

$$t_{ODLY\_H} + t_{DATA\_DELAY} + t_{TAP\_DELAY} + t_{ISU} < t_{WL} + t_{CLK\_DELAY}$$

(9)

$$t_{DATA\_DELAY} + t_{TAP\_DELAY} - t_{CLK\_DELAY} < t_{WL} - t_{ISU} - t_{ODLY\_H}$$

$$t_{DATA\_DELAY} - t_{CLK\_DELAY} < t_{WL} - t_{ISU} - t_{ODLY\_H} - t_{TAP\_DELAY}$$

$$t_{DATA\_DELAY} - t_{CLK\_DELAY} < 10 - 6 - 14 - t_{TAP\_DELAY}$$

$$t_{DATA\_DELAY} - t_{CLK\_DELAY} < -10 - t_{TAP\_DELAY}$$

The data delay is less than the clock delay by at least 10 ns in the ideal case where t_{WL}= 10 ns.

High-Speed Write Meeting Hold (Minimum Delay)

The following equations show how to calculate the allowed skew range between the SD_CLK and SD_DAT/CMD signals on the PCB.

(10)

$$t_{CLK\_DELAY} < t_{WL} + t_{OH\_H} + t_{DATA\_DELAY} + t_{TAP\_DELAY} - t_{IH}$$

$$t_{CLK\_DELAY} - t_{DATA\_DELAY} < t_{WL} + t_{OH\_H} + t_{TAP\_DELAY} - t_{IH}$$

$$t_{CLK\_DELAY} - t_{DATA\_DELAY} < 10 + 2 + t_{TAP\_DELAY} - 2$$

$$t_{CLK\_DELAY} - t_{DATA\_DELAY} < 10 + t_{TAP\_DELAY}$$

The clock can be delayed versus data up to 13.2 ns (external delay line) in ideal case of t_{WL}= 10 ns, with maximum t_{TAP_DELAY} = 3.2 ns programmed.
