### Understanding [Embedded - CPLDs \(Complex Programmable Logic Devices\)](#)

Embedded - CPLDs, or Complex Programmable Logic Devices, are highly versatile digital logic devices used in electronic systems. These programmable components are designed to perform complex logical operations and can be customized for specific applications. Unlike fixed-function ICs, CPLDs offer the flexibility to reprogram their configuration, making them an ideal choice for various embedded systems. They consist of a set of logic gates and programmable interconnects, allowing designers to implement complex logic circuits without needing custom hardware.

## Features

- **HIGH-DENSITY PROGRAMMABLE LOGIC**
  - 8000 PLD Gates
  - 96 I/O Pins, Ten Dedicated Inputs
  - 288 Registers
  - High-Speed Global Interconnects
  - Wide Input Gating for Fast Counters, State Machines, Address Decoders, etc.
  - Small Logic Block Size for Random Logic
  - Security Cell Prevents Unauthorized Copying
- **HIGH PERFORMANCE E<sup>2</sup>CMOS<sup>®</sup> TECHNOLOGY**
  - $f_{max} = 80$  MHz Maximum Operating Frequency
  - $f_{max} = 50$  MHz for Industrial Devices
  - $t_{pd} = 15$  ns Propagation Delay
  - TTL Compatible Inputs and Outputs
  - Electrically Erasable and Reprogrammable
  - Non-Volatile E<sup>2</sup>CMOS Technology
  - 100% Tested
- **IN-SYSTEM PROGRAMMABLE**
  - In-System Programmable<sup>™</sup> (ISP<sup>™</sup>) 5-Volt Only
  - Increased Manufacturing Yields, Reduced Time-to-Market, and Improved Product Quality
  - Reprogram Soldered Devices for Faster Debugging
- **COMBINES EASE OF USE AND THE FAST SYSTEM SPEED OF PLDs WITH THE DENSITY AND FLEXIBILITY OF FIELD PROGRAMMABLE GATE ARRAYS**
  - Complete Programmable Device Can Combine Glue Logic and Structured Designs
  - Four Dedicated Clock Input Pins
  - Synchronous and Asynchronous Clocks
  - Flexible Pin Placement
  - Optimized Global Routing Pool Provides Global Interconnectivity

## Functional Block Diagram

## Description

The ispLSI 1048 is a High-Density Programmable Logic Device which contains 288 Registers, 96 Universal I/O pins, ten Dedicated Input pins, four Dedicated Clock Input pins and a Global Routing Pool (GRP). The GRP provides complete interconnectivity between all of these elements. The ispLSI 1048 features 5-Volt in-system programming and in-system diagnostic capabilities. It is the first device which offers non-volatile reprogrammability of the logic, as well as the interconnect to provide truly reconfigurable systems.

The basic unit of logic on the ispLSI 1048 devices is the Generic Logic Block (GLB). The GLBs are labeled A0, A1 .. F7 (see figure 1). There are a total of 48 GLBs in the ispLSI 1048 device. Each GLB has 18 inputs, a programmable AND/OR/XOR array, and four outputs which can be configured to be either combinatorial or registered. Inputs to the GLB come from the GRP and dedicated inputs. All of the GLB outputs are brought back into the GRP so that they can be connected to the inputs of any other GLB on the device.

## Functional Block Diagram

Figure 1. ispLSI 1048 Functional Block Diagram

The device also has 96 I/O cells, each of which is directly connected to an I/O pin. Each I/O cell can be individually programmed to be a combinatorial input, registered input, latched input, output or bi-directional I/O pin with 3-state control. Additionally, all outputs are polarity selectable, active high or active low. The signal levels are TTL compatible voltages and the output drivers can source 4 mA or sink 8 mA.

Eight GLBs, 16 I/O cells, two dedicated inputs (one dedicated input in Megablock B and E) and one ORP are connected together to make a Megablock (see figure 1). The outputs of the eight GLBs are connected to a set of 16 universal I/O cells by the ORP. The ispLSI 1048 device contains six of these Megablocks.

The GRP has as its inputs the outputs from all of the GLBs and all of the inputs from the bi-directional I/O cells. All of these signals are made available to the inputs of the GLBs. Delays through the GRP have been equalized to minimize timing skew.

Clocks in the ispLSI 1048 device are selected using the Clock Distribution Network. Four dedicated clockpins (Y0, Y1, Y2 and Y3) are brought into the distribution network, and five clock outputs (CLK 0, CLK 1, CLK 2, IOCLK 0 and IOCLK 1) are provided to route clocks to the GLBs and I/O cells. The Clock Distribution Network can also be driven from a special clock GLB (D0 on the ispLSI 1048 device). The logic of this GLB allows the user to create an internal clock from a combination of internal signals within the device.

## Absolute Maximum Ratings <sup>1</sup>

Supply Voltage  $V_{CC}$  ..... -0.5 to +7.0V

Input Voltage Applied ..... -2.5 to  $V_{CC} + 1.0V$

Off-State Output Voltage Applied ..... -2.5 to  $V_{CC} + 1.0V$

Storage Temperature ..... -65 to 150°C

Case Temp. with Power Applied ..... -55 to 125°C

Max. Junction Temp. ( $T_J$ ) with Power Applied ... 150°C

1. Stresses above those listed under the "Absolute Maximum Ratings" may cause permanent damage to the device. Functional operation of the device at these or at any other conditions above those indicated in the operational sections of this specification is not implied (while programming, follow the programming specifications).

### Maximum GRP Delay vs GLB Loads

0126A-48-80-isp

### Power Consumption

Power consumption in the ispLSI 1048 device depends on two primary factors: the speed at which the device is operating, and the number of Product Terms used. Figure 3 shows the relationship between power and operating speed.

**Figure 3. Typical Device Power Consumption vs fmax**

Notes: Configuration of Twelve 16-bit Counters  
Typical Current at 5V, 25°C

$I_{CC}$  can be estimated for the ispLSI 1048 using the following equation:

$$I_{CC} = 73 + (\# \text{ of PTs} \times 0.23) + (\# \text{ of nets} \times \text{Max. freq} \times 0.010) \text{ where:}$$

# of PTs = Number of Product Terms used in design

# of nets = Number of Signals used in device

Max. freq = Highest Clock Frequency to the device

The  $I_{CC}$  estimate is based on typical conditions ( $V_{CC} = 5.0V$ , room temperature) and an assumption of 2 GLB loads on average exists. These values are for estimates only. Since the value of  $I_{CC}$  is sensitive to operating conditions and the program in the device, the actual  $I_{CC}$  should be verified.

This pin is brought low to enable the programming mode. The MODE, SDI, SDO and SCLK options become active.</p> <p>Input – This pin performs two functions. It is a dedicated input pin when <math>\overline{\text{ispEN}}</math> is logic high. When <math>\overline{\text{ispEN}}</math> is logic low, it functions as an input pin to load programming data into the device. SDI/IN 0 also is used as one of the two control pins for the isp state machine.</p> <p>Input – This pin performs two functions. It is a dedicated input pin when <math>\overline{\text{ispEN}}</math> is logic high. When <math>\overline{\text{ispEN}}</math> is logic low, it functions as a pin to control the operation of the isp state machine.</p> <p>Input/Output – This pin performs two functions. It is a dedicated input pin when <math>\overline{\text{ispEN}}</math> is logic high. When <math>\overline{\text{ispEN}}</math> is logic low, it functions as an output pin to read serial shift register data.</p> <p>Input – This pin performs two functions.
