Welcome to E-XFL.COM

What is "**Embedded - Microcontrollers**"?

"Embedded - Microcontrollers" refer to small, integrated circuits designed to perform specific tasks within larger systems. These microcontrollers are essentially compact computers on a single chip, containing a processor core, memory, and programmable input/output peripherals. They are called "embedded" because they are embedded within electronic devices to control various functions, rather than serving as standalone computers. Microcontrollers are crucial in modern electronics, providing the intelligence and control needed for a wide range of applications.

Applications of "**Embedded - Microcontrollers**"

Details	
Product Status	Obsolete
Core Processor	eZ8
Core Size	8-Bit
Speed	5MHz
Connectivity	IrDA, UART/USART
Peripherals	Brown-out Detect/Reset, LED, POR, PWM, WDT
Number of I/O	24
Program Memory Size	2KB (2K x 8)
Program Memory Type	FLASH
EEPROM Size	-
RAM Size	512 x 8
Voltage - Supply (Vcc/Vdd)	2.7V ~ 3.6V
Data Converters	-
Oscillator Type	Internal
Operating Temperature	-40°C ~ 105°C (TA)
Mounting Type	Surface Mount
Package / Case	28-SSOP (0.173", 4.40mm Width)
Supplier Device Package	-
Purchase URL	https://www.e-xfl.com/product-detail/zilog/z8f0213hj005eg

Table 8. Register File Address Map (Continued)

Address (Hex)	Register Description	Mnemonic	Reset (Hex)	Page No.
LED Controller (cont'd)				
F84	LED Drive Level Low Byte	LEDLVLL	00	53

GPIO Port B				
FD4	Port B Address	PBADDR	00	40
FD5	Port B Control	PBCTL	00	42

Note: XX=Undefined.

Reset and Stop Mode Recovery

The Reset Controller within the Z8 Encore! XP F0823 Series controls Reset and Stop Mode Recovery operation and provides indication of low supply voltage conditions. In typical operation, the following events cause a Reset:

- Power-On Reset (POR)
- Voltage Brown-Out (VBO)
- Watchdog Timer time-out (when configured by the WDT_RES Flash Option Bit to initiate a reset)
- External $\overline{\text{RESET}}$ pin assertion (when the alternate RESET function is enabled by the GPIO register)
- On-chip Debugger initiated Reset (OCDCTL[0] set to 1)

When the device is in STOP Mode, a Stop Mode Recovery is initiated by either of the following:

- Watchdog Timer time-out
- GPIO port input pin transition on an enabled Stop Mode Recovery source

The VBO circuitry on the device performs the following function:

- Generates the VBO reset when the supply voltage drops below a minimum safe level

Reset Types

F0823 Series MCUs provide several different types of Reset operations. Stop Mode Recovery is considered a form of Reset. Table 9 lists the types of Reset and their operating characteristics. The duration of a System Reset is longer if the external crystal oscillator is enabled by the Flash option bits; this configuration allows additional time for oscillator startup.

Table 9. Reset and Stop Mode Recovery Characteristics and Latency

Reset Type	Reset Characteristics and Latency		
	Control Registers	eZ8 CPU	Reset Latency (Delay)
System Reset	Reset (as applicable)	Reset	66 Internal Precision Oscillator Cycles
Stop Mode Recovery	Unaffected, except WDT_CTL and OSC_CTL registers	Reset	66 Internal Precision Oscillator Cycles + IPO startup time

Table 17. Port Alternate Function Mapping (Non 8-Pin Parts)

Port	Pin	Mnemonic	Alternate Function Description	Alternate Function Set Register AFS1
Port A[1]	PA0	T0IN/T0OUT	Timer 0 Input/Timer 0 Output Complement	N/A
		Reserved		
	PA1	T0OUT	Timer 0 Output	
		Reserved		
	PA2	DE0	UART 0 Driver Enable	
		Reserved		
	PA3	CTS0	UART 0 Clear to Send	
		Reserved		
	PA4	RXD0/IRRX0	UART 0 / IrDA 0 Receive Data	
		Reserved		
	PA5	TXD0/IRTX0	UART 0 / IrDA 0 Transmit Data	
		Reserved		
	PA6	T1IN/T1OUT[2]	Timer 1 Input/Timer 1 Output Complement	
		Reserved		
	PA7	T1OUT	Timer 1 Output	
		Reserved		

Notes:
1. Because there is only a single alternate function for each Port A pin, the Alternate Function Set registers are not implemented for Port A. Enabling alternate function selections as described in the <u>Port A–C Alternate Function Subregisters</u> section on page 43 automatically enables the associated alternate function.
2. Whether PA0/PA6 take on the timer input or timer output complement function depends on the timer configuration as described in the <u>Timer Pin Signal Operation</u> section on page 83.
3. Because there are at most two choices of alternate function for any pin of Port B, the Alternate Function Set register AFS2 is implemented but not used to select the function. Also, alternate function selection as described in the <u>Port A–C Alternate Function Subregisters</u> section on page 43 must also be enabled.
4. V_{REF} is available on PB5 in 28-pin products only.
5. Because there are at most two choices of alternate function for any pin of Port C, the Alternate Function Set register AFS2 is implemented but not used to select the function. Also, Alternate Function selection as described in the <u>Port A–C Alternate Function Subregisters</u> section on page 43 must also be enabled.
6. V_{REF} is available on PC2 in 20-pin parts only.

Table 17. Port Alternate Function Mapping (Non 8-Pin Parts) (Continued)

Port	Pin	Mnemonic	Alternate Function Description	Alternate Function Set Register AFS1
Port B[3]	PB03	Reserved		AFS1[0]: 0
		ANA0	ADC Analog Input	AFS1[0]: 1
	PB1	Reserved		AFS1[1]: 0
		ANA1	ADC Analog Input	AFS1[1]: 1
	PB2	Reserved		AFS1[2]: 0
		ANA2	ADC Analog Input	AFS1[2]: 1
	PB3	CLKIN	External Clock Input	AFS1[3]: 0
		ANA3	ADC Analog Input	AFS1[3]: 1
	PB4	Reserved		AFS1[4]: 0
		ANA7	ADC Analog Input	AFS1[4]: 1
	PB5	Reserved		AFS1[5]: 0
		V_{REF}[4]	ADC Voltage Reference	AFS1[5]: 1
	PB6	Reserved		AFS1[6]: 0
		Reserved		AFS1[6]: 1
	PB7	Reserved		AFS1[7]: 0
		Reserved		AFS1[7]: 1

Notes:
1. Because there is only a single alternate function for each Port A pin, the Alternate Function Set registers are not implemented for Port A. Enabling alternate function selections as described in the Port A–C Alternate Function Subregisters section on page 43 automatically enables the associated alternate function.
2. Whether PA0/PA6 take on the timer input or timer output complement function depends on the timer configuration as described in the Timer Pin Signal Operation section on page 83.
3. Because there are at most two choices of alternate function for any pin of Port B, the Alternate Function Set register AFS2 is implemented but not used to select the function. Also, alternate function selection as described in the Port A–C Alternate Function Subregisters section on page 43 must also be enabled.
4. V_{REF} is available on PB5 in 28-pin products only.
5. Because there are at most two choices of alternate function for any pin of Port C, the Alternate Function Set register AFS2 is implemented but not used to select the function. Also, Alternate Function selection as described in the Port A–C Alternate Function Subregisters section on page 43 must also be enabled.
6. V_{REF} is available on PC2 in 20-pin parts only.

Port A–C Input Data Registers

Reading from the Port A–C Input Data registers (Table 30) returns the sampled values from the corresponding port pins. The Port A–C Input Data registers are read-only. The value returned for any unused ports is 0. Unused ports include those missing on the 8- and 28-pin packages, as well as those missing on the ADC-enabled 28-pin packages.

Table 30. Port A–C Input Data Registers (PxIN)

Bit	7	6	5	4	3	2	1	0
Field	PIN7	PIN6	PIN5	PIN4	PIN3	PIN2	PIN1	PIN0
RESET	X	X	X	X	X	X	X	X
R/W	R	R	R	R	R	R	R	R
Address	FD2H, FD6H, FDAH							

Bit	Description
[7:0] PxIN	**Port Input Data** Sampled data from the corresponding port pin input. 0 = Input data is logical 0 (Low). 1 = Input data is logical 1 (High).

Note: x indicates the specific GPIO port pin number (7–0).

Also, if the Timer Output alternate function is enabled, the Timer Output pin changes state for one system clock cycle (from Low to High or from High to Low) upon timer reload. If it is appropriate to have the Timer Output make a state change at a One-Shot time-out (rather than a single cycle pulse), first set the TPOL bit in the Timer Control Register to the start value before enabling ONE-SHOT Mode. After starting the timer, set TPOL to the opposite bit value.

Observe the following steps to configure a timer for ONE-SHOT Mode and initiating the count:

1. Write to the Timer Control Register to:
    –   Disable the timer
    –   Configure the timer for ONE-SHOT Mode
    –   Set the prescale value
    –   Set the initial output level (High or Low) if using the Timer Output alternate function

2. Write to the Timer High and Low Byte registers to set the starting count value.

3. Write to the Timer Reload High and Low Byte registers to set the reload value.

4. If appropriate, enable the timer interrupt and set the timer interrupt priority by writing to the relevant interrupt registers.

5. If using the Timer Output function, configure the associated GPIO port pin for the Timer Output alternate function.

6. Write to the Timer Control Register to enable the timer and initiate counting.

In ONE-SHOT Mode, the system clock always provides the timer input. The timer period is computed via the following equation:

$$\text{ONE-SHOT Mode Time-Out Period (s)} = \frac{(\text{Reload Value} - \text{Start Value}) \times \text{Prescale}}{\text{System Clock Frequency (Hz)}}$$

CONTINUOUS Mode

In CONTINUOUS Mode, the timer counts up to the 16-bit reload value stored in the Timer Reload High and Low Byte registers. The timer input is the system clock. Upon reaching the reload value, the timer generates an interrupt, the count value in the Timer High and Low Byte registers is reset to 0001H and counting resumes. Also, if the Timer Output alternate function is enabled, the Timer Output pin changes state (from Low to High or from High to Low) at timer reload.

Observe the following steps to configure a timer for CONTINUOUS Mode and to initiate the count:

1. Write to the Timer Control Register to:
   – Disable the timer
   – Configure the timer for CONTINUOUS Mode
   – Set the prescale value
   – If using the Timer Output alternate function, set the initial output level (High or Low)

2. Write to the Timer High and Low Byte registers to set the starting count value (usually `0001H`). This action only affects the first pass in CONTINUOUS Mode. After the first timer reload in CONTINUOUS Mode, counting always begins at the reset value of `0001H`.

3. Write to the Timer Reload High and Low Byte registers to set the reload value.

4. Enable the timer interrupt (if appropriate) and set the timer interrupt priority by writing to the relevant interrupt registers.

5. Configure the associated GPIO port pin (if using the Timer Output function) for the Timer Output alternate function.

6. Write to the Timer Control Register to enable the timer and initiate counting.

In CONTINUOUS Mode, the system clock always provides the timer input. The timer period is computed via the following equation:

$$\text{CONTINUOUS Mode Time-Out Period (s)} = \frac{\text{Reload Value} \times \text{Prescale}}{\text{System Clock Frequency (Hz)}}$$

If an initial starting value other than `0001H` is loaded into the Timer High and Low Byte registers, use the ONE-SHOT Mode equation to determine the first time-out period.

COUNTER Mode

In COUNTER Mode, the timer counts input transitions from a GPIO port pin. The timer input is taken from the GPIO port pin Timer Input alternate function. The `TPOL` bit in the Timer Control Register selects whether the count occurs on the rising edge or the falling edge of the timer input signal. In COUNTER Mode, the prescaler is disabled.

! **Caution:** The input frequency of the timer input signal must not exceed one-fourth the system clock frequency.

Upon reaching the reload value stored in the Timer Reload High and Low Byte registers, the timer generates an interrupt, the count value in the Timer High and Low Byte registers is reset to `0001H` and counting resumes. Also, if the Timer Output alternate function is

input capture and reload events. If appropriate, configure the timer interrupt to be generated only at the input capture event or the reload event by setting TICONFIG field of the TxCTL1 Register.

6. Configure the associated GPIO port pin for the Timer Input alternate function.

7. Write to the Timer Control Register to enable the timer and initiate counting.

In CAPTURE Mode, the elapsed time from timer start to capture event can be calculated using the following equation:

$$\text{Capture Elapsed Time (s)} = \frac{(\text{Capture Value} - \text{Start Value}) \times \text{Prescale}}{\text{System Clock Frequency (Hz)}}$$

CAPTURE RESTART Mode

In CAPTURE RESTART Mode, the current timer count value is recorded when the acceptable external Timer Input transition occurs. The capture count value is written to the Timer PWM High and Low Byte registers. The timer input is the system clock. The TPOL bit in the Timer Control Register determines if the capture occurs on a rising edge or a falling edge of the Timer Input signal. When the capture event occurs, an interrupt is generated and the count value in the Timer High and Low Byte registers is reset to 0001H and counting resumes. The INPCAP bit in TxCTL1 Register is set to indicate the timer interrupt is because of an input capture event.

If no capture event occurs, the timer counts up to the 16-bit compare value stored in the Timer Reload High and Low Byte registers. Upon reaching the reload value, the timer generates an interrupt, the count value in the Timer High and Low Byte registers is reset to 0001H and counting resumes. The INPCAP bit in TxCTL1 Register is cleared to indicate the timer interrupt is not caused by an input capture event.

Observe the following steps to configure a timer for CAPTURE RESTART Mode and initiating the count:

1. Write to the Timer Control Register to:
   – Disable the timer
   – Configure the timer for CAPTURE RESTART Mode; setting the mode also involves writing to TMODEHI bit in TxCTL1 Register
   – Set the prescale value
   – Set the capture edge (rising or falling) for the Timer Input

2. Write to the Timer High and Low Byte registers to set the starting count value (typically 0001H).

3. Write to the Timer Reload High and Low Byte registers to set the reload value.

4. Clear the Timer PWM High and Low Byte registers to `0000H`. Clearing these registers allows the software to determine if interrupts were generated by either a capture or a reload event. If the PWM High and Low Byte registers still contain `0000H` after the interrupt, the interrupt was generated by a reload.

5. Enable the timer interrupt, if appropriate, and set the timer interrupt priority by writing to the relevant interrupt registers. By default, the timer interrupt is generated for both input capture and reload events. If appropriate, configure the timer interrupt to be generated only at the input capture event or the reload event by setting TICONFIG field of the TxCTL1 Register.

6. Configure the associated GPIO port pin for the Timer Input alternate function.

7. Write to the Timer Control Register to enable the timer and initiate counting.

In CAPTURE Mode, the elapsed time from timer start to capture event can be calculated using the following equation:

$$\text{Capture Elapsed Time (s)} = \frac{(\text{Capture Value} - \text{Start Value}) \times \text{Prescale}}{\text{System Clock Frequency (Hz)}}$$

COMPARE Mode

In COMPARE Mode, the timer counts up to the 16-bit maximum compare value stored in the Timer Reload High and Low Byte registers. The timer input is the system clock. Upon reaching the compare value, the timer generates an interrupt and counting continues (the timer value is not reset to `0001H`). Also, if the Timer Output alternate function is enabled, the Timer Output pin changes state (from Low to High or from High to Low) upon compare.

If the Timer reaches `FFFFH`, the timer rolls over to `0000H` and continue counting. Observe the following steps to configure a timer for COMPARE Mode and to initiate the count:

1. Write to the Timer Control Register to:
   – Disable the timer
   – Configure the timer for COMPARE Mode
   – Set the prescale value
   – Set the initial logic level (High or Low) for the Timer Output alternate function, if appropriate

2. Write to the Timer High and Low Byte registers to set the starting count value.

3. Write to the Timer Reload High and Low Byte registers to set the compare value.

4. Enable the timer interrupt, if appropriate, and set the timer interrupt priority by writing to the relevant interrupt registers.

Universal Asynchronous Receiver/ Transmitter

The universal asynchronous receiver/transmitter (UART) is a full-duplex communication channel capable of handling asynchronous data transfers. The UART uses a single 8-bit data mode with selectable parity. The features of UART include:

- 8-bit asynchronous data transfer

- Selectable even- and odd-parity generation and checking

- Option of one or two STOP bits

- Separate transmit and receive interrupts

- Framing, parity, overrun, and break detection

- Separate transmit and receive enables

- 16-bit baud rate generator (BRG)

- Selectable MULTIPROCESSOR (9-bit) Mode with three configurable interrupt schemes

- BRG can be configured and used as a basic 16-bit timer

- Driver Enable output for external bus transceivers

Architecture

The UART consists of three primary functional blocks: transmitter, receiver, and baud rate generator. The UART's transmitter and receiver function independently, but employ the same baud rate and data format. Figure 10 displays the UART architecture.

1. Checks the UART Status 0 Register to determine the source of the interrupt - error, break, or received data.

2. Reads the data from the UART Receive Data Register if the interrupt was because of data available. If operating in MULTIPROCESSOR (9-bit) Mode, further actions may be required depending on the MULTIPROCESSOR Mode bits MPMD[1:0].

3. Clears the UART Receiver interrupt in the applicable Interrupt Request register.

4. Executes the IRET instruction to return from the interrupt-service routine and await more data.

Clear To Send ($\overline{\text{CTS}}$) Operation

The CTS pin, if enabled by the CTSE bit of the UART Control 0 Register, performs flow control on the outgoing transmit datastream. The Clear To Send ($\overline{\text{CTS}}$) input pin is sampled one system clock before beginning any new character transmission. To delay transmission of the next data character, an external receiver must deassert $\overline{\text{CTS}}$ at least one system clock cycle before a new data transmission begins. For multiple character transmissions, this action is typically performed during Stop Bit transmission. If $\overline{\text{CTS}}$ deasserts in the middle of a character transmission, the current character is sent completely.

MULTIPROCESSOR (9-Bit) Mode

The UART has a MULTIPROCESSOR (9-bit) Mode that uses an extra (9th) bit for selective communication when a number of processors share a common UART bus. In MULTIPROCESSOR Mode (also referred to as 9-bit mode), the multiprocessor bit (MP) is transmitted immediately following the 8-bits of data and immediately preceding the Stop bit(s) as displayed in Figure 13. The character format is given below:
Figure 13. UART Asynchronous MULTIPROCESSOR Mode Data Format

In MULTIPROCESSOR (9-bit) Mode, the parity bit location (9th bit) becomes the Multiprocessor control bit. The UART Control 1 and Status 1 registers provide MULTIPROCESSOR (9-bit) Mode control and status information. If an automatic address matching

scheme is enabled, the UART Address Compare register holds the network address of the device.

MULTIPROCESSOR (9-bit) Mode Receive Interrupts

When MULTIPROCESSOR Mode is enabled, the UART only processes frames addressed to it. The determination of whether a frame of data is addressed to the UART can be made in hardware, software or some combination of the two, depending on the multiprocessor configuration bits. In general, the address compare feature reduces the load on the CPU, because it does not require access to the UART when it receives data directed to other devices on the multi-node network. The following three MULTIPROCESSOR modes are available in hardware:

- Interrupt on all address bytes

- Interrupt on matched address bytes and correctly framed data bytes

- Interrupt only on correctly framed data bytes

These modes are selected with MPMD[1:0] in the UART Control 1 Register. For all multi-processor modes, bit MPEN of the UART Control 1 Register must be set to 1.

The first scheme is enabled by writing 01b to MPMD[1:0]. In this mode, all incoming address bytes cause an interrupt, while data bytes never cause an interrupt. The interrupt service routine must manually check the address byte that caused triggered the interrupt. If it matches the UART address, the software clears MPMD[0]. Each new incoming byte interrupts the CPU. The software is responsible for determining the end of the frame. It checks for the end-of-frame by reading the MPRX bit of the UART Status 1 Register for each incoming byte. If MPRX=1, a new frame has begun. If the address of this new frame is different from the UART's address, MPMD[0] must be set to 1 causing the UART inter-rupts to go inactive until the next address byte. If the new frame's address matches the UART's, the data in the new frame is processed as well.

The second scheme requires the following: set MPMD[1:0] to 10B and write the UART's address into the UART Address Compare register. This mode introduces additional hard-ware control, interrupting only on frames that match the UART's address. When an incoming address byte does not match the UART's address, it is ignored. All successive data bytes in this frame are also ignored. When a matching address byte occurs, an inter-rupt is issued and further interrupts now occur on each successive data byte. When the first data byte in the frame is read, the NEWFRM bit of the UART Status 1 Register is asserted. All successive data bytes have NEWFRM=0. When the next address byte occurs, the hard-ware compares it to the UART's address. If there is a match, the interrupts continues and the NEWFRM bit is set for the first byte of the new frame. If there is no match, the UART ignores all incoming bytes until the next address match.

The third scheme is enabled by setting MPMD[1:0] to 11b and by writing the UART's address into the UART Address Compare Register. This mode is identical to the second

UART Status 0 Register

The UART Status 0 and Status 1 registers (Table 66 and Table 67) identify the current UART operating configuration and status.

Table 66. UART Status 0 Register (U0STAT0)

Bit	7	6	5	4	3	2	1	0
Field	RDA	PE	OE	FE	BRKD	TDRE	TXE	CTS
RESET	0	0	0	0	0	1	1	X
R/W	R	R	R	R	R	R	R	R
Address	F41H							

| Bit	Description
[7] RDA	**Receive Data Available** This bit indicates that the UART Receive Data Register has received data. Reading the UART Receive Data Register clears this bit. 0 = The UART Receive Data Register is empty. 1 = There is a byte in the UART Receive Data Register.
[6] PE	**Parity Error** This bit indicates that a parity error has occurred. Reading the UART Receive Data register clears this bit. 0 = No parity error has occurred. 1 = A parity error has occurred.
[5] OE	**Overrun Error** This bit indicates that an overrun error has occurred. An overrun occurs when new data is received and the UART Receive Data Register has not been read. If the RDA bit is reset to 0, reading the UART Receive Data Register clears this bit. 0 = No overrun error occurred. 1 = An overrun error occurred.
[4] FE	**Framing Error** This bit indicates that a framing error (no Stop bit following data reception) was detected. Reading the UART Receive Data Register clears this bit. 0 = No framing error occurred. 1 = A framing error occurred.
[3] BRKD	**Break Detect** This bit indicates that a break occurred. If the data bits, parity/multiprocessor bit, and Stop bit(s) are all 0s this bit is set to 1. Reading the UART Receive Data Register clears this bit. 0 = No break occurred. 1 = A break occurred.

passed to the UART. Communication is half-duplex, which means simultaneous data transmission and reception is not allowed.

The baud rate is set by the UART's baud rate generator and supports IrDA standard baud rates from 9600 baud to 115.2 kbaud. Higher baud rates are possible, but do not meet IrDA specifications. The UART must be enabled to use the infrared endec. The infrared endec data rate is calculated using the following equation:

$$\text{Infrared Data Rate (bits/s)} = \frac{\text{System Clock Frequency (Hz)}}{16 \times \text{UART Baud Rate Divisor Value}}$$

Transmitting IrDA Data

The data to be transmitted using the infrared transceiver is first sent to the UART. The UART's transmit signal (TXD) and baud rate clock are used by the IrDA to generate the modulation signal (IR_TXD) that drives the infrared transceiver. Each UART/Infrared data bit is 16 clocks wide. If the data to be transmitted is 1, the IR_TXD signal remains low for the full 16 clock period. If the data to be transmitted is 0, the transmitter first outputs a 7 clock low period, followed by a 3 clock high pulse. Finally, a 6 clock low pulse is output to complete the full 16 clock data period. Figure 17 displays IrDA data transmission. When the infrared endec is enabled, the UART's TXD signal is internal to Z8 Encore! XP F0823 Series products while the IR_TXD signal is output through the TXD pin.
Figure 17. Infrared Data Transmission

ADC Control/Status Register 1

The second ADC Control Register contains the voltage reference level selection bit.

Table 75. ADC Control/Status Register 1 (ADCCTL1)

Bit	7	6	5	4	3	2	1	0
Field	REFSELH	Reserved						
RESET	1	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Address	F71H							

Bit	Description
[7] REFSELH	**Voltage Reference Level Select High Bit** In conjunction with the Low bit (REFSELL) in ADC Control Register 0, this bit determines the level of the internal voltage reference; the following details the effects of {REFSELH, REFSELL}; this reference is independent of the Comparator reference. 00 = Internal Reference Disabled, reference comes from external pin. 01 = Internal Reference set to 1.0V. 10 = Internal Reference set to 2.0V (default).
[6:0]	**Reserved** These bits are reserved and must be programmed to 0000000.

Page Erase

The Flash memory can be erased one page (512 bytes) at a time. Page Erasing the Flash memory sets all bytes in that page to the value FFH. The Flash Page Select register identifies the page to be erased. Only a page residing in an unprotected sector can be erased. With the Flash Controller unlocked and the active page set, writing the value 95h to the Flash Control Register initiates the Page Erase operation. While the Flash Controller executes the Page Erase operation, the eZ8 CPU idles but the system clock and on-chip peripherals continue to operate. The eZ8 CPU resumes operation after the Page Erase operation completes. If the Page Erase operation is performed using the On-Chip Debugger, poll the Flash Status Register to determine when the Page Erase operation is complete. When the Page Erase is complete, the Flash Controller returns to its locked state.

Mass Erase

The Flash memory can also be Mass Erased using the Flash Controller, but only by using the On-Chip Debugger. Mass Erasing the Flash memory sets all bytes to the value FFH. With the Flash Controller unlocked and the Mass Erase successfully enabled, writing the value 63H to the Flash Control Register initiates the Mass Erase operation. While the Flash Controller executes the Mass Erase operation, the eZ8 CPU idles but the system clock and on-chip peripherals continue to operate. Using the On-Chip Debugger, poll the Flash Status Register to determine when the Mass Erase operation is complete. When the Mass Erase is complete, the Flash Controller returns to its locked state.

Flash Controller Bypass

The Flash Controller can be bypassed and the control signals for the Flash memory brought out to the GPIO pins. Bypassing the Flash Controller allows faster Row Programming algorithms by controlling the Flash programming signals directly.

Row programing is recommended for gang programming applications and large volume customers who do not require in-circuit initial programming of the Flash memory. Page Erase operations are also supported when the Flash Controller is bypassed.

For more information about bypassing the Flash Controller, refer to the Zilog application note titled, Third-Party Flash Programming Support for Z8 Encore! MCUs (AN0117), available for download at www.zilog.com.

Flash Controller Behavior in DEBUG Mode

The following changes in behavior of the Flash Controller occur when the Flash Controller is accessed using the On-Chip Debugger:

• The Flash Write Protect option bit is ignored

• The Flash Sector Protect register is ignored for programming and erase operations

> **⚠ Caution:** Unintentional accesses to the Oscillator Control Register can actually stop the chip by switching to a non-functioning oscillator. To prevent this condition, the oscillator control block employs a register unlocking/locking scheme.

OSC Control Register Unlocking/Locking

To write to the Oscillator Control Register, unlock it by making two writes to the OSC-CTL Register with the values E7H followed by 18H. A third write to the OSCCTL Register changes the value of the actual register and returns the register to a locked state. Any other sequence of Oscillator Control Register writes has no effect. The values written to unlock the register must be ordered correctly, but are not necessarily consecutive. It is possible to write to or read from other registers within the unlocking/locking operation.

When selecting a new clock source, the primary oscillator failure detection circuitry and the Watchdog Timer oscillator failure circuitry must be disabled. If POFEN and WOFEN are not disabled prior to a clock switch-over, it is possible to generate an interrupt for a failure of either oscillator. The Failure detection circuitry can be enabled anytime after a successful write of OSCSEL in the Oscillator Control Register.

The internal precision oscillator is enabled by default. If the user code changes to a different oscillator, it is appropriate to disable the IPO for power savings. Disabling the IPO does not occur automatically.

Clock Failure Detection and Recovery

Should an oscillator or timer fail, there are methods of recovery, as this section describes.

Primary Oscillator Failure

Z8 Encore! XP F0823 Series devices can generate non-maskable interrupt-like events when the primary oscillator fails. To maintain system function in this situation, the clock failure recovery circuitry automatically forces the Watchdog Timer oscillator to drive the system clock. The Watchdog Timer oscillator must be enabled to allow the recovery. Although this oscillator runs at a much slower speed than the original system clock, the CPU continues to operate, allowing execution of a clock failure vector and software routines that either remedy the oscillator failure or issue a failure alert. This automatic switch-over is not available if the Watchdog Timer is the primary oscillator. It is also unavailable if the Watchdog Timer oscillator is disabled, though it is not necessary to enable the Watchdog Timer reset function outlined in the the <u>Watchdog Timer</u> section on page 91.

The primary oscillator failure detection circuitry asserts if the system clock frequency drops below 1 kHz ±50%. If an external signal is selected as the system oscillator, it is possible that a very slow but non-failing clock can generate a failure condition. Under these

Table 108. Notational Shorthand (Continued)

Notation	Description	Operand	Range
RA	Relative Address	X	X represents an index in the range of +127 to –128 which is an offset relative to the address of the next instruction
rr	Working Register Pair	RRp	p = 0, 2, 4, 6, 8, 10, 12, or 14.
RR	Register Pair	Reg	Reg. represents an even number in the range of 00H to FEH.
Vector	Vector Address	Vector	Vector represents a number in the range of 00H to FFH.
X	Indexed	#Index	The register or register pair to be indexed is offset by the signed Index value (#Index) in a +127 to –128 range.

Table 109 lists additional symbols that are used throughout the Instruction Summary and Instruction Set Description sections.

Table 109. Additional Symbols

Symbol	Definition
dst	Destination Operand
src	Source Operand
@	Indirect Address Prefix
SP	Stack Pointer
PC	Program Counter
FLAGS	Flags Register
RP	Register Pointer
#	Immediate Operand Prefix
B	Binary Number Suffix
%	Hexadecimal Number Prefix
H	Hexadecimal Number Suffix

Assignment of a value is indicated by an arrow, as shown in the following example.

$$dst \leftarrow dst + src$$

This example indicates that the source data is added to the destination data; the result is stored in the destination location.

Table 115. Logical Instructions

Mnemonic	Operands	Instruction
AND	dst, src	Logical AND
ANDX	dst, src	Logical AND using Extended Addressing
COM	dst	Complement
OR	dst, src	Logical OR
ORX	dst, src	Logical OR using Extended Addressing
XOR	dst, src	Logical Exclusive OR
XORX	dst, src	Logical Exclusive OR using Extended Addressing

Table 116. Program Control Instructions

Mnemonic	Operands	Instruction
BRK	—	On-Chip Debugger Break
BTJ	p, bit, src, DA	Bit Test and Jump
BTJNZ	bit, src, DA	Bit Test and Jump if Non-Zero
BTJZ	bit, src, DA	Bit Test and Jump if Zero
CALL	dst	Call Procedure
DJNZ	dst, src, RA	Decrement and Jump Non-Zero
IRET	—	Interrupt Return
JP	dst	Jump
JP cc	dst	Jump Conditional
JR	DA	Jump Relative
JR cc	DA	Jump Relative Conditional
RET	—	Return
TRAP	vector	Software Trap

Table 117. Rotate and Shift Instructions

Mnemonic	Operands	Instruction
BSWAP	dst	Bit Swap
RL	dst	Rotate Left
RLC	dst	Rotate Left through Carry
