

Welcome to [E-XFL.COM](#)

What is "[Embedded - Microcontrollers](#)"?

"[Embedded - Microcontrollers](#)" refer to small, integrated circuits designed to perform specific tasks within larger systems. These microcontrollers are essentially compact computers on a single chip, containing a processor core, memory, and programmable input/output peripherals. They are called "embedded" because they are embedded within electronic devices to control various functions, rather than serving as standalone computers. Microcontrollers are crucial in modern electronics, providing the intelligence and control needed for a wide range of applications.

Applications of "[Embedded - Microcontrollers](#)"

Details

Product Status	Active
Core Processor	eZ8
Core Size	8-Bit
Speed	5MHz
Connectivity	IrDA, UART/USART
Peripherals	Brown-out Detect/Reset, LED, POR, PWM, WDT
Number of I/O	6
Program Memory Size	2KB (2K x 8)
Program Memory Type	FLASH
EEPROM Size	-
RAM Size	512 x 8
Voltage - Supply (Vcc/Vdd)	2.7V ~ 3.6V
Data Converters	A/D 4x10b
Oscillator Type	Internal
Operating Temperature	0°C ~ 70°C (TA)
Mounting Type	Surface Mount
Package / Case	8-VDFN Exposed Pad
Supplier Device Package	8-QFN (5x6)
Purchase URL	https://www.e-xfl.com/product-detail/zilog/z8f0223qb005sg

Figure 32. UART Timing With CTS 208

Figure 33. UART Timing Without CTS 209

► **Note:** *Analog input alternate functions (ANA) are not available on Z8F0x13 devices.

Signal Descriptions

Table 3 lists the Z8 Encore! XP F0823 Series signals. To determine the signals available for the specific package styles, see the [Pin Configurations](#) section on page 7.

Table 3. Signal Descriptions

Signal Mnemonic	I/O	Description
General-Purpose I/O Ports A–D		
PA[7:0]	I/O	Port A. These pins are used for general-purpose I/O.
PB[7:0] ¹	I/O	Port B. These pins are used for general-purpose I/O. PB6 and PB7 are available only in those devices without an ADC.
PC[7:0]	I/O	Port C. These pins are used for general-purpose I/O.
UART Controllers		
TXD0	O	Transmit Data. This signal is the transmit output from the UART and IrDA.
RXD0	I	Receive Data. This signal is the receive input for the UART and IrDA.
CTS0	I	Clear To Send. This signal is the flow control input for the UART.
DE	O	Driver Enable. This signal allows automatic control of external RS-485 drivers. This signal is approximately the inverse of the TXE (Transmit Empty) bit in the UART Status 0 Register. The DE signal can be used to ensure the external RS-485 driver is enabled when data is transmitted by the UART.
Timers		
T0OUT/T1OUT	O	Timer Output 0–1. These signals are output from the timers.
T0OUT/T1OUT	O	Timer Complement Output 0–1. These signals are output from the timers in PWM DUAL OUTPUT Mode.
T0IN/T1IN	I	Timer Input 0–1. These signals are used as the capture, gating and counter inputs. The T0IN signal is multiplexed T0OUT signals.
Comparator		
CINP/CINN	I	Comparator Inputs. These signals are the positive and negative inputs to the comparator.

Notes:

1. PB6 and PB7 are only available in 28-pin packages without ADC. In 28-pin packages with ADC, they are replaced by AV_{DD} and AV_{SS}.
2. The AV_{DD} and AV_{SS} signals are available only in 28-pin packages with ADC. They are replaced by PB6 and PB7 on 28-pin packages without ADC.

The eZ8 CPU fetches the Reset vector at Program Memory addresses 0002H and 0003H and loads that value into the Program Counter. Program execution begins at the Reset vector address. Following Stop Mode Recovery, the STOP bit in the Watchdog Timer Control Register is set to 1. Table 11 lists the Stop Mode Recovery sources and resulting actions. The section following the table provides more detailed information about each of the Stop Mode Recovery sources.

Table 11. Stop Mode Recovery Sources and Resulting Action

Operating Mode	Stop Mode Recovery Source	Action
STOP Mode	Watchdog Timer time-out when configured for Reset	Stop Mode Recovery
	Watchdog Timer time-out when configured for interrupt	Stop Mode Recovery followed by interrupt (if interrupts are enabled)
	Data transition on any GPIO port pin enabled as a Stop Mode Recovery source	Stop Mode Recovery
	Assertion of external RESET Pin	System Reset
	Debug Pin driven Low	System Reset

Stop Mode Recovery Using Watchdog Timer Time-Out

If the Watchdog Timer times out during STOP Mode, the device undergoes a Stop Mode Recovery sequence. In the Watchdog Timer Control Register, the WDT and STOP bits are set to 1. If the Watchdog Timer is configured to generate an interrupt upon time-out and Z8 Encore! XP F0823 Series device is configured to respond to interrupts, the eZ8 CPU services the Watchdog Timer interrupt request following the normal Stop Mode Recovery sequence.

Stop Mode Recovery Using a GPIO Port Pin Transition

Each of the GPIO port pins can be configured as a Stop Mode Recovery input source. On any GPIO pin enabled as a Stop Mode Recovery source, a change in the input pin value (from High to Low or from Low to High) initiates Stop Mode Recovery.

► **Note:** The SMR pulses shorter than specified does not trigger a recovery. When this happens, the STOP bit in the Reset Status (RSTSTAT) Register is set to 1.

! **Caution:** In STOP Mode, the GPIO Port Input Data registers (PxIN) are disabled. The Port Input Data registers record the port transition only if the signal stays on the port pin through the end of the Stop Mode Recovery delay. As a result, short pulses on the port pin can initiate Stop Mode Recovery without being written to the Port Input Data Register or without initiating an interrupt (if enabled for that pin).

Table 18. GPIO Port Registers and Subregisters (Continued)

Port Register Mnemonic	Port Register Name
PxHDE	High Drive Enable.
PxSMRE	Stop Mode Recovery Source Enable.
PxPUE	Pull-up Enable.
PxAFS1	Alternate Function Set 1.
PxAFS2	Alternate Function Set 2.

Port A–C Address Registers

The Port A–C Address registers select the GPIO port functionality accessible through the Port A–C Control registers. The Port A–C Address and Control registers combine to provide access to all GPIO port controls (Table 19).

Table 19. Port A–C GPIO Address Registers (PxADDR)

Bit	7	6	5	4	3	2	1	0
Field	PADDR[7:0]							
RESET	00H							
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Address	FD0H, FD4H, FD8H							

Bit	Description
[7:0] PADDR	Port Address The Port Address selects one of the subregisters accessible through the Port Control Register. See Table 20 for each subregister function.

Table 20. PADDR[7:0] Subregister Functions

PADDR[7:0]	Port Control Subregister Accessible Using the Port A–C Control Registers
00H	No function. Provides some protection against accidental Port reconfiguration.
01H	Data Direction.
02H	Alternate Function.
03H	Output Control (Open-Drain).
04H	High Drive Enable.

Interrupt Request 2 Register

The Interrupt Request 2 (IRQ2) register (Table 38) stores interrupt requests for both vectored and polled interrupts. When a request is presented to the interrupt controller, the corresponding bit in the IRQ2 Register becomes 1. If interrupts are globally enabled (vectored interrupts), the interrupt controller passes an interrupt request to the eZ8 CPU. If interrupts are globally disabled (polled interrupts), the eZ8 CPU can read the Interrupt Request 2 Register to determine if any interrupt requests are pending.

Table 38. Interrupt Request 2 Register (IRQ2)

Bit	7	6	5	4	3	2	1	0
Field	Reserved				PC3I	PC2I	PC1I	PC0I
RESET	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Address	FC6H							

Bit	Description
[7:4]	Reserved These bits are reserved and must be programmed to 0000.
[3:0] PCxI	Port C Pin x Interrupt Request 0 = No interrupt request is pending for GPIO Port C pin x. 1 = An interrupt request from GPIO Port C pin x is awaiting service.

Note: x indicates the specific GPIO Port C pin number (3–0).

IRQ0 Enable High and Low Bit Registers

Table 39 describes the priority control for IRQ0. The IRQ0 Enable High and Low Bit registers (Table 40 and Table 41) form a priority-encoded enabling for interrupts in the Interrupt Request 0 Register. Priority is generated by setting bits in each register.

Table 39. IRQ0 Enable and Priority Encoding

IRQ0ENH[x]	IRQ0ENL[x]	Priority	Description
0	0	Disabled	Disabled
0	1	Level 1	Low
1	0	Level 2	Nominal
1	1	Level 3	High

Note: where x indicates the register bits from 0–7.

Table 47. IRQ2 Enable Low Bit Register (IRQ2ENL)

Bit	7	6	5	4	3	2	1	0
Field	Reserved				C3ENL	C2ENL	C1ENL	C0ENL
RESET	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Address	FC8H							

Bit	Description
[7:4]	Reserved These bits are reserved and must be programmed to 0000.
[3] C3ENL	Port C3 Interrupt Request Enable Low Bit
[2] C2ENL	Port C2 Interrupt Request Enable Low Bit
[1] C1ENL	Port C1 Interrupt Request Enable Low Bit
[0] C0ENL	Port C0 Interrupt Request Enable High Low

Interrupt Edge Select Register

The Interrupt Edge Select (IRQES) Register (Table 48) determines whether an interrupt is generated for the rising edge or falling edge on the selected GPIO Port A or Port D input pin.

Table 48. Interrupt Edge Select Register (IRQES)

Bit	7	6	5	4	3	2	1	0
Field	IES7	IES6	IES5	IES4	IES3	IES2	IES1	IES0
RESET	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Address	FCDH							

Bit	Description
[7] IESx	Interrupt Edge Select x 0 = An interrupt request is generated on the falling edge of the PAX input or PDx. 1 = An interrupt request is generated on the rising edge of the PAX input PDx.

Note: x indicates the specific GPIO port pin number (7–0).

1. Write to the Timer Control Register to:
 - Disable the timer
 - Configure the timer for CONTINUOUS Mode
 - Set the prescale value
 - If using the Timer Output alternate function, set the initial output level (High or Low)
2. Write to the Timer High and Low Byte registers to set the starting count value (usually 0001H). This action only affects the first pass in CONTINUOUS Mode. After the first timer reload in CONTINUOUS Mode, counting always begins at the reset value of 0001H.
3. Write to the Timer Reload High and Low Byte registers to set the reload value.
4. Enable the timer interrupt (if appropriate) and set the timer interrupt priority by writing to the relevant interrupt registers.
5. Configure the associated GPIO port pin (if using the Timer Output function) for the Timer Output alternate function.
6. Write to the Timer Control Register to enable the timer and initiate counting.

In CONTINUOUS Mode, the system clock always provides the timer input. The timer period is computed via the following equation:

$$\text{CONTINUOUS Mode Time-Out Period (s)} = \frac{\text{Reload Value} \times \text{Prescale}}{\text{System Clock Frequency (Hz)}}$$

If an initial starting value other than 0001H is loaded into the Timer High and Low Byte registers, use the ONE-SHOT Mode equation to determine the first time-out period.

COUNTER Mode

In COUNTER Mode, the timer counts input transitions from a GPIO port pin. The timer input is taken from the GPIO port pin Timer Input alternate function. The TPOL bit in the Timer Control Register selects whether the count occurs on the rising edge or the falling edge of the timer input signal. In COUNTER Mode, the prescaler is disabled.

! Caution: The input frequency of the timer input signal must not exceed one-fourth the system clock frequency.

Upon reaching the reload value stored in the Timer Reload High and Low Byte registers, the timer generates an interrupt, the count value in the Timer High and Low Byte registers is reset to 0001H and counting resumes. Also, if the Timer Output alternate function is

two bits to configure timer interrupt definition, and a status bit to identify if the most recent timer interrupt is caused by an input capture event.

Table 57. Timer 0–1 Control Register 0 (TxCTL0)

Bit	7	6	5	4	3	2	1	0
Field	TMODEHI	TICONFIG		Reserved	PWMD			INPCAP
RESET	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Address	F06H, F0EH							

Bit	Description
[7] TMODEHI	Timer Mode High Bit This bit along with the TMODE field in TxCTL1 Register determines the operating mode of the timer. This is the most-significant bit of the Timer mode selection value.
[6:5] TICONFIG	Timer Interrupt Configuration This field configures timer interrupt definition. 0x = Timer Interrupt occurs on all defined reload, compare and input events. 10 = Timer Interrupt only on defined input capture/deassertion events. 11 = Timer Interrupt only on defined reload/compare events.
[4] 	Reserved This bit is reserved and must be programmed to 0.
[3:1] PWMD	PWMD—PWM Delay value This field is a programmable delay to control the number of system clock cycles delay before the Timer Output and the Timer Output Complement are forced to their active state. 000 = No delay. 001 = 2 cycles delay. 010 = 4 cycles delay. 011 = 8 cycles delay. 100 = 16 cycles delay. 101 = 32 cycles delay. 110 = 64 cycles delay. 111 = 128 cycles delay.
[0] INPCAP	Input Capture Event This bit indicates if the most recent timer interrupt is caused by a Timer Input capture event. 0 = Previous timer interrupt is not a result of Timer Input capture event. 1 = Previous timer interrupt is a result of Timer Input capture event.

Timer 0–1 Control Register 1

The Timer 0–1 Control (TxCTL1) registers enable/disable the timers, set the prescaler value, and determine the timer operating mode.

Watchdog Timer

The Watchdog Timer (WDT) protects against corrupt or unreliable software, power faults, and other system-level problems which can place Z8 Encore! XP F0823 Series devices into unsuitable operating states. The features of Watchdog Timer include:

- On-chip RC oscillator
- A selectable time-out response: reset or interrupt
- 24-bit programmable time-out value

Operation

The WDT is a retriggerable one-shot timer that resets or interrupts F0823 Series devices when the WDT reaches its terminal count. The Watchdog Timer uses a dedicated on-chip RC oscillator as its clock source. The Watchdog Timer operates in only two modes: ON and OFF. Once enabled, it always counts and must be refreshed to prevent a time-out. Perform an enable by executing the WDT instruction or by setting the WDT_AO Flash Option Bit. The WDT_AO bit forces the Watchdog Timer to operate immediately upon reset, even if a WDT instruction has not been executed.

The Watchdog Timer is a 24-bit reloadable down counter that uses three 8-bit registers in the eZ8 CPU register space to set the reload value. The nominal WDT time-out period is described by the following equation:

$$\text{WDT Time-out Period (ms)} = \frac{\text{WDT Reload Value}}{10}$$

where the WDT reload value is the decimal value of the 24-bit value given by {WDTU[7:0], WDTM[7:0], WDTL[7:0]} and the typical Watchdog Timer RC oscillator frequency is 10kHz. The Watchdog Timer cannot be refreshed after it reaches 000002H. The WDT Reload Value must not be set to values below 000004H. Table 59 provides information about approximate time-out delays for the minimum and maximum WDT reload values.

Table 59. Watchdog Timer Approximate Time-Out Delays

WDT Reload Value (Hex)	WDT Reload Value (Decimal)	Approximate Time-Out Delay (with 10kHz typical WDT oscillator frequency)	
		Typical	Description
000004	4	400 μ s	Minimum time-out delay
FFFFFF	16,777,215	28 minutes	Maximum time-out delay

Watchdog Timer Reload High Byte Register (WDTH): see page 95

Watchdog Timer Reload Low Byte Register (WDTL): see page 95

Watchdog Timer Control Register

The Watchdog Timer Control (WDTCTL) register is a write-only control register. Writing the 55H, AAH unlock sequence to the WDTCTL Register address unlocks the three Watchdog Timer Reload Byte registers (WDTU, WDTH and WDTL) to allow changes to the time-out period. These write operations to the WDTCTL Register address produce no effect on the bits in the WDTCTL Register. The locking mechanism prevents spurious writes to the Reload registers.

This register address is shared with the read-only Reset Status Register.

Table 60. Watchdog Timer Control Register (WDTCTL)

Bit	7	6	5	4	3	2	1	0
Field	WDTUNLK							
RESET	X	X	X	X	X	X	X	X
R/W	W	W	W	W	W	W	W	W
Address	FF0H							

Bit	Description
[7:0]	Watchdog Timer Unlock
WDTUNLK	The software must write the correct unlocking sequence to this register before it is allowed to modify the contents of the Watchdog Timer reload registers.

Watchdog Timer Reload Upper, High and Low Byte Registers

The Watchdog Timer Reload Upper, High and Low Byte (WDTU, WDTH, WDTL) registers, shown in Tables 61 through 63, form the 24-bit reload value that is loaded into the Watchdog Timer when a WDT instruction executes. The 24-bit reload value ranges across bits [23:0] to encompass the three bytes {WDTU[7:0], WDTH[7:0], WDTL[7:0]}. Writing to these registers sets the appropriate Reload Value. Reading from these registers returns the current Watchdog Timer count value.

! Caution: The 24-bit WDT Reload Value must not be set to a value less than 000004H.

Figure 10. UART Block Diagram

Operation

The UART always transmits and receives data in an 8-bit data format, least-significant bit (lsb) first. An even or odd parity bit can be added to the data stream. Each character begins with an active Low Start bit and ends with either 1 or 2 active High Stop bits. Figure 11 and Figure 12 display the asynchronous data format employed by the UART without parity and with parity, respectively.

Infrared Encoder/Decoder

Z8 Encore! XP F0823 Series products contain a fully-functional, high-performance UART with an infrared encoder/decoder (endec). The infrared endec is integrated with an on-chip UART to allow easy communication between the Z8 Encore! XP and IrDA Physical Layer Specification, Version 1.3-compliant infrared transceivers. Infrared communication provides secure, reliable, low-cost, point-to-point communication between PCs, PDAs, cell phones, printers and other infrared enabled devices.

Architecture

Figure 16 displays the architecture of the infrared endec.

Figure 16. Infrared Data Communication System Block Diagram

Operation

When the infrared endec is enabled, the transmit data from the associated on-chip UART is encoded as digital signals in accordance with the IrDA standard and output to the infrared transceiver through the TXD pin. Similarly, data received from the infrared transceiver is passed to the infrared endec through the RXD pin, decoded by the infrared endec, and

bits can only be set to 1. Thus, sectors can be protected, but not unprotected, via register write operations. Writing a value other than 5EH to the Flash Control Register deselects the Flash Sector Protect Register and reenables access to the Page Select Register.

Observe the following procedure to setup the Flash Sector Protect Register from user code:

1. Write 00H to the Flash Control Register to reset the Flash Controller.
2. Write 5EH to the Flash Control Register to select the Flash Sector Protect Register.
3. Read and/or write the Flash Sector Protect Register which is now at Register File address FF9H.
4. Write 00H to the Flash Control Register to return the Flash Controller to its reset state.

The Sector Protect Register is initialized to 0 on reset, putting each sector into an unprotected state. When a bit in the Sector Protect Register is written to 1, the corresponding sector can no longer be written or erased by the CPU. External Flash programming through the OCD or via the Flash Controller Bypass mode are unaffected. After a bit of the Sector Protect Register has been set, it cannot be cleared except by powering down the device.

Byte Programming

The Flash Memory is enabled for byte programming after unlocking the Flash Controller and successfully enabling either Mass Erase or Page Erase. When the Flash Controller is unlocked and Mass Erase is successfully completed, all Program Memory locations are available for byte programming. In contrast, when the Flash Controller is unlocked and Page Erase is successfully enabled, only the locations of the selected page are available for byte programming. An erased Flash byte contains all 1's (FFH). The programming operation can only be used to change bits from 1 to 0. To change a Flash bit (or multiple bits) from 0 to 1 requires execution of either the Page Erase or Mass Erase commands.

Byte Programming is accomplished using the On-Chip Debugger's Write Memory command or eZ8 CPU execution of the LDC or LDCI instructions. For a description of the LDC and LDCI instructions, refer to the eZ8 CPU Core User Manual (UM0128), available for download at www.zilog.com. While the Flash Controller programs the Flash memory, the eZ8 CPU idles but the system clock and on-chip peripherals continue to operate. To exit programming mode and lock the Flash, write any value to the Flash Control Register, except the Mass Erase or Page Erase commands.

! Caution: The byte at each address of the Flash memory cannot be programmed (any bits written to 0) more than twice before an erase cycle occurs. Doing so may result in corrupted data at the target byte.

- Programming operations are not limited to the page selected in the Page Select register
- Bits in the Flash Sector Protect register can be written to one or zero
- The second write of the Page Select register to unlock the Flash Controller is not necessary
- The Page Select register can be written when the Flash Controller is unlocked
- The Mass Erase command is enabled through the Flash Control Register

! **Caution:** For security reasons, the Flash Controller allows only a single page to be opened for write/erase. When writing multiple Flash pages, the Flash controller must repeat the unlock sequence to select another page.

Flash Control Register Definitions

This section defines the features of the following Flash Control registers.

Flash Control Register: see page 141

Flash Status Register: see page 143

Flash Page Select Register: see page 143

Flash Sector Protect Register: see page 145

Flash Frequency High and Low Byte Registers: see page 145

Flash Control Register

The Flash Controller must be unlocked using the Flash Control (FTCTL) Register before programming or erasing the Flash memory. Writing the sequence 73H 8CH, sequentially, to the Flash Control Register unlocks the Flash Controller. When the Flash Controller is unlocked, the Flash memory can be enabled for Mass Erase or Page Erase by writing the appropriate enable command to the FCTL. Page Erase applies only to the active page selected in Flash Page Select register. Mass Erase is enabled only through the On-Chip Debugger. Writing an invalid value or an invalid sequence returns the Flash Controller to its locked state. The Write-only Flash Control Register shares its Register File address with the read-only Flash Status Register.

Trim Bit Data Register

The Trim Bid Data (TRMDR) register contains the read or write data for access to the trim option bits.

Table 88. Trim Bit Data Register (TRMDR)

Bit	7	6	5	4	3	2	1	0
Field	TRMDR: Trim Bit Data							
RESET	0	0	0	0	0	0	0	0
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Address	FF7H							

Flash Option Bit Address Space

The first two bytes of Flash program memory at addresses 0000H and 0001H are reserved for the user-programmable Flash option bits.

Table 89. Flash Option Bits at Program Memory Address 0000H

Bit	7	6	5	4	3	2	1	0
Field	WDT_RES	WDT_AO	Reserved		VBO_AO	FRP	Reserved	FWP
RESET	U	U	U	U	U	U	U	U
R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W	R/W
Address	Program Memory 0000H							
Note: U = Unchanged by Reset. R/W = Read/Write.								

Bit	Description
[7] WDT_RES	Watchdog Timer Reset 0 = Watchdog Timer time-out generates an interrupt request. Interrupts must be globally enabled for the eZ8 CPU to acknowledge the interrupt request. 1 = Watchdog Timer time-out causes a system reset. This setting is the default for unprogrammed (erased) Flash.
[6] WDT_AO	Watchdog Timer Always ON 0 = Watchdog Timer is automatically enabled upon application of system power. Watchdog Timer can not be disabled. 1 = Watchdog Timer is enabled upon execution of the WDT instruction. Once enabled, the Watchdog Timer can only be disabled by a Reset or Stop Mode Recovery. This setting is the default for unprogrammed (erased) Flash.
[5:4]	Reserved These bits are reserved and must be programmed to 11 during writes, and to 11 when read.

- If the PA2/ $\overline{\text{RESET}}$ pin is held Low while a 32-bit key sequence is issued to the PA0/DBG pin, the DBG feature is unlocked. After releasing PA2/ $\overline{\text{RESET}}$, it is pulled high. At this point, the PA0/DBG pin can be used to autobaud and cause the device to enter DEBUG Mode. For more details, see the OCD Unlock Sequence (8-Pin Devices Only) section on page 161.

Exiting DEBUG Mode

The device exits DEBUG Mode following any of these operations:

- Clearing the DBGMODE bit in the OCD Control Register to 0
- Power-On Reset
- Voltage Brown-Out reset
- Watchdog Timer reset
- Asserting the $\overline{\text{RESET}}$ pin Low to initiate a Reset
- Driving the DBG pin Low while the device is in STOP Mode initiates a system reset

OCD Data Format

The OCD interface uses the asynchronous data format defined for RS-232. Each character is transmitted as 1 Start bit, 8 data bits (least-significant bit first), and 1 Stop bit as displayed in Figure 25.

Figure 25. OCD Data Format

► **Note:** When responding to a request for data, the OCD may commence transmitting immediately after receiving the stop bit of an incoming frame. Therefore, when sending the stop bit, the host must not actively drive the DBG pin High for more than 0.5 bit times. Zilog recommends that, if possible, the host drives the DBG pin using an open-drain output.

OCD Autobaud Detector/Generator

To run over a range of baud rates (data bits per second) with various system clock frequencies, the OCD contains an auto-baud detector/generator. After a reset, the OCD is idle until it receives data. The OCD requires that the first character sent from the host is the character 80H. The character 80H has eight continuous bits Low (one Start bit plus 7 data

eZ8 CPU Instruction Set

This chapter describes the following features of the eZ8 CPU instruction set:

Assembly Language Programming Introduction: see page 174

Assembly Language Syntax: see page 175

eZ8 CPU Instruction Notation: see page 176

eZ8 CPU Instruction Classes: see page 178

eZ8 CPU Instruction Summary: see page 182

Assembly Language Programming Introduction

The eZ8 CPU assembly language provides a means for writing an application program without concern for actual memory addresses or machine instruction formats. A program written in assembly language is called a source program. Assembly language allows the use of symbolic addresses to identify memory locations. It also allows mnemonic codes (opcodes and operands) to represent the instructions themselves. The opcodes identify the instruction while the operands represent memory locations, registers, or immediate data values.

Each assembly language program consists of a series of symbolic commands called *statements*. Each statement can contain labels, operations, operands, and comments.

Labels are assigned to a particular instruction step in a source program. The label identifies that step in the program as an entry point for use by other instructions.

The assembly language also includes assembler directives that supplement the machine instruction. The assembler directives, or pseudo-ops, are not translated into a machine instruction. Rather, the pseudo-ops are interpreted as directives that control or assist the assembly process.

The source program is processed (assembled) by the assembler to obtain a machine language program called the object code. The object code is executed by the eZ8 CPU. An example segment of an assembly language program is detailed in the following example.

Table 117. Rotate and Shift Instructions (Continued)

Mnemonic	Operands	Instruction
RR	dst	Rotate Right
RRC	dst	Rotate Right through Carry
SRA	dst	Shift Right Arithmetic
SRL	dst	Shift Right Logical
SWAP	dst	Swap Nibbles

eZ8 CPU Instruction Summary

Table 118 summarizes the eZ8 CPU instruction set. The table identifies the addressing modes employed by the instruction, the effect upon the Flags Register, the number of CPU clock cycles required for the instruction fetch, and the number of CPU clock cycles required for the instruction execution.

Table 118. eZ8 CPU Instruction Summary

Assembly Mnemonic	Symbolic Operation	Address Mode		Opcode(s) (Hex)	Flags						Fetch Cycles	Instr. Cycles
		dst	src		C	Z	S	V	D	H		
ADC dst, src	$\text{dst} \leftarrow \text{dst} + \text{src} + \text{C}$	r	r	12	*	*	*	*	0	*	2	3
		r	lr	13							2	4
		R	R	14							3	3
		R	IR	15							3	4
		R	IM	16							3	3
		IR	IM	17							3	4
ADCX dst, src	$\text{dst} \leftarrow \text{dst} + \text{src} + \text{C}$	ER	ER	18	*	*	*	*	0	*	4	3
		ER	IM	19							4	3

Note: Flags Notation:

* = Value is a function of the result of the operation.

– = Unaffected.

X = Undefined.

0 = Reset to 0.

1 = Set to 1.

On-Chip Peripheral AC and DC Electrical Characteristics

Table 125 tabulates the electrical characteristics of the POR and VBO blocks.

Table 125. Power-On Reset and Voltage Brown-Out Electrical Characteristics and Timing

Symbol	Parameter	$T_A = -40^{\circ}\text{C to } +105^{\circ}\text{C}$			Units	Conditions
		Minimum	Typical*	Maximum		
V_{POR}	Power-On Reset Voltage Threshold	2.20	2.45	2.70	V	$V_{\text{DD}} = V_{\text{POR}}$
V_{VBO}	Voltage Brown-Out Reset Voltage Threshold	2.15	2.40	2.65	V	$V_{\text{DD}} = V_{\text{VBO}}$
	V_{POR} to V_{VBO} hysteresis		50	75	mV	
	Starting V_{DD} voltage to ensure valid Power-On Reset.	—	V_{SS}	—	V	
T_{ANA}	Power-On Reset Analog Delay	—	70	—	μs	$V_{\text{DD}} > V_{\text{POR}}$; T_{POR} Digital Reset delay follows T_{ANA}
T_{POR}	Power-On Reset Digital Delay		16		μs	66 Internal Precision Oscillator cycles + IPO startup time (T_{IPOST})
T_{SMR}	Stop Mode Recovery		16		μs	66 Internal Precision Oscillator cycles
T_{VBO}	Voltage Brown-Out Pulse Rejection Period	—	10	—	μs	Period of time in which $V_{\text{DD}} < V_{\text{VBO}}$ without generating a Reset.
T_{RAMP}	Time for V_{DD} to transition from V_{SS} to V_{POR} to ensure valid Reset	0.10	—	100	ms	
T_{SMP}	Stop Mode Recovery pin pulse rejection period		20		ns	For any SMR pin or for the Reset pin when it is asserted in STOP Mode.

Note: *Data in the typical column is from characterization at 3.3 V and 30°C. These values are provided for design guidance only and are not tested in production.
