

Welcome to E-XFL.COM

What is "Embedded - Microcontrollers"?

"Embedded - Microcontrollers" refer to small, integrated circuits designed to perform specific tasks within larger systems. These microcontrollers are essentially compact computers on a single chip, containing a processor core, memory, and programmable input/output peripherals. They are called "embedded" because they are embedded within electronic devices to control various functions, rather than serving as standalone computers. Microcontrollers are crucial in modern electronics, providing the intelligence and control needed for a wide range of applications.

Applications of "<u>Embedded -</u> <u>Microcontrollers</u>"

Details

Product Status	Obsolete
Core Processor	eZ8
Core Size	8-Bit
Speed	5MHz
Connectivity	IrDA, UART/USART
Peripherals	Brown-out Detect/Reset, LED, POR, PWM, WDT
Number of I/O	22
Program Memory Size	2KB (2K x 8)
Program Memory Type	FLASH
EEPROM Size	-
RAM Size	512 x 8
Voltage - Supply (Vcc/Vdd)	2.7V ~ 3.6V
Data Converters	A/D 8x10b
Oscillator Type	Internal
Operating Temperature	-40°C ~ 105°C (TA)
Mounting Type	Surface Mount
Package / Case	28-SOIC (0.295", 7.50mm Width)
Supplier Device Package	-
Purchase URL	https://www.e-xfl.com/product-detail/zilog/z8f0223sj005eg

Email: info@E-XFL.COM

Address: Room A, 16/F, Full Win Commercial Centre, 573 Nathan Road, Mongkok, Hong Kong

Address Space

The eZ8 CPU can access three distinct address spaces:

- The Register File contains addresses for the general-purpose registers and the eZ8 CPU, peripheral, and general-purpose I/O Port Control Registers
- The Program Memory contains addresses for all memory locations having executable code and/or data
- The Data Memory contains addresses for all memory locations that contain data only

These three address spaces are covered briefly in the following subsections. For more detailed information regarding the eZ8 CPU and its address space, refer to the <u>eZ8 CPU</u> <u>Core User Manual (UM0128)</u>, available for download at <u>www.zilog.com</u>.

Register File

The Register File address space in the Z8 Encore! XP[™] MCU is 4KB (4096 bytes). The Register File is composed of two sections: control registers and general-purpose registers. When instructions are executed, registers defined as sources are read, and registers defined as destinations are written. The architecture of the eZ8 CPU allows all general-purpose registers to function as accumulators, address pointers, index registers, stack areas, or scratch pad memory.

The upper 256 bytes of the 4KB Register File address space are reserved for control of the eZ8 CPU, the on-chip peripherals, and the I/O ports. These registers are located at addresses from F00H to FFFH. Some of the addresses within the 256 B control register section are reserved (unavailable). Reading from a reserved Register File address returns an undefined value. Writing to reserved Register File addresses is not recommended and can produce unpredictable results.

The on-chip RAM always begins at address 000H in the Register File address space. Z8 Encore! XP F0823 Series devices contain 256B–1KB of on-chip RAM. Reading from Register File addresses outside the available RAM addresses (and not within the control register address space) returns an undefined value. Writing to these Register File addresses produces no effect.

Program Memory

The eZ8 CPU supports 64KB of Program Memory address space. F0823 Series devices contain 1KB to 8KB of on-chip Flash memory in the Program Memory address space. Reading from Program Memory addresses outside the available Flash memory addresses

returns FFH. Writing to these unimplemented Program Memory addresses produces no effect. Table 6 describes the Program Memory maps for the Z8 Encore! XP F0823 Series products.

Program Memory Address (Hex)	Function
Z8F0823 and Z8F0813 Products	
0000–0001	Flash Option Bits

Port A–C High Drive Enable Subregisters

The Port A–C High Drive Enable Subregister (Table 25) is accessed through the Port A–C Control Register by writing 04H to the Port A–C Address Register. Setting the bits in the Port A–C High Drive Enable subregisters to 1 configures the specified port pins for high-current output drive operation. The Port A–C High Drive Enable Subregister affects the pins directly and, as a result, alternate functions are also affected.

Table 25. Port A–C High Drive Enable Subregiste	ers (PHDEx)

PHDEx 0 = The Port pin is configured for standard output current drive.

1 = The Port pin is configured for high output current drive.

Note: x indicates the specific GPIO port pin number (7–0).

Embedded in Life

Shared Interrupt Select Register

The Shared Interrupt Select (IRQSS) register (Table 49) determines the source of the PADxS interrupts. The Shared Interrupt Select register selects between Port A and alternate sources for the individual interrupts.

Because these shared interrupts are edge-triggered, it is possible to generate an interrupt just by switching from one shared source to another. For this reason, an interrupt must be disabled before switching between sources.

Bit	7	6	5	4	3	2	1	0

Table 49. Shared Interrupt Select Register (IRQSS)

Bit	Description
[7]	Reserved This bit is reserved and must be programmed to 0.
[6] PA6CS	 PA6/Comparator Selection 0 = PA6 is used for the interrupt for PA6CS interrupt request. 1 = The comparator is used as an interrupt for PA6CS interrupt requests.
[5:0]	Reserved These bits are reserved and must be programmed to 000000.

Observe the following steps to configure a timer for PWM DUAL OUTPUT Mode and initiating the PWM operation:

- 1. Write to the Timer Control Register to:
 - Disable the timer
 - Configure the timer for PWM DUAL OUTPUT Mode. Setting the mode also involves writing to the TMODEHI bit in the TxCTL1 Register
 - Set the prescale value
 - Set the initial logic level (High or Low) and PWM High/Low transition for the Timer Output alternate function
- 2. Write to the Timer High and Low Byte registers to set the starting count value (typically 0001H); this write only affects the first pass in PWM Mode. After the first timer reset in PWM Mode, counting always begins at the reset value of 0001H.
- 3. Write to the PWM High and Low Byte registers to set the PWM value.
- 4. Write to the PWM Control Register to set the PWM dead band delay value. The deadband delay must be less than the duration of the positive phase of the PWM signal (as defined by the PWM high and low byte registers). It must also be less than the duration of the negative phase of the PWM signal (as defined by the difference between the PWM registers and the Timer Reload registers).
- 5. Write to the Timer Reload High and Low Byte registers to set the reload value (PWM period). The reload value must be greater than the PWM value.
- 6. If appropriate, enable the timer interrupt and set the timer interrupt priority by writing to the relevant interrupt registers.
- 7. Configure the associated GPIO port pin for the Timer Output and Timer Output Complement alternate functions. The Timer Output Complement function is shared with the Timer Input function for both timers. Setting the timer mode to Dual PWM automatically switches the function from Timer In to Timer Out Complement.
- 8. Write to the Timer Control Register to enable the timer and initiate counting.

The PWM period is represented by the following equation:

PWM Period (s) = $\frac{\text{Reload Value } \times \text{Prescale}}{\text{System Clock Frequency (Hz)}}$

If an initial starting value other than 0001H is loaded into the Timer High and Low Byte registers, the ONE-SHOT Mode equation determines the first PWM time-out period.

If TPOL is set to 0, the ratio of the PWM output High time to the total period is represented by:

WDT Reset in NORMAL Operation

If configured to generate a Reset when a time-out occurs, the Watchdog Timer forces the device into the System Reset state. The WDT status bit in the Watchdog Timer Control Register is set to 1. For more information about System Reset, see **the** <u>Reset and Stop</u> <u>Mode Recovery</u> chapter on page 21.

WDT Reset in STOP Mode

If configured to generate a Reset when a time-out occurs and the device is in STOP Mode, the Watchdog Timer initiates a Stop Mode Recovery. Both the WDT status bit and the STOP bit in the Watchdog Timer Control Register are set to 1 following WDT time-out in STOP Mode. For more information, see **the** <u>Reset and Stop Mode Recovery</u> chapter on page 21.

Watchdog Timer Reload Unlock Sequence

Writing the unlock sequence to the Watchdog Timer Control Register (WDTCTL) address unlocks the three Watchdog Timer Reload Byte Registers (WDTU, WDTH, and WDTL) to allow changes to the time-out period. These write operations to the WDTCTL Register address produce no effect on the bits in the WDTCTL Register. The locking mechanism prevents spurious writes to the Reload registers. The following sequence is required to unlock the Watchdog Timer Reload Byte Registers (WDTU, WDTH, and WDTL) for write access.

- 1. Write 55H to the Watchdog Timer Control Register (WDTCTL).
- 2. Write AAH to the Watchdog Timer Control Register (WDTCTL).
- 3. Write the Watchdog Timer Reload Upper Byte register (WDTU).
- 4. Write the Watchdog Timer Reload High Byte register (WDTH).
- 5. Write the Watchdog Timer Reload Low Byte register (WDTL).

All three Watchdog Timer Reload registers must be written in the order just listed. There must be no other register writes between each of these operations. If a register write occurs, the lock state machine resets and no further writes can occur unless the sequence is restarted. The value in the Watchdog Timer Reload registers is loaded into the counter when the Watchdog Timer is first enabled and every time a WDT instruction is executed.

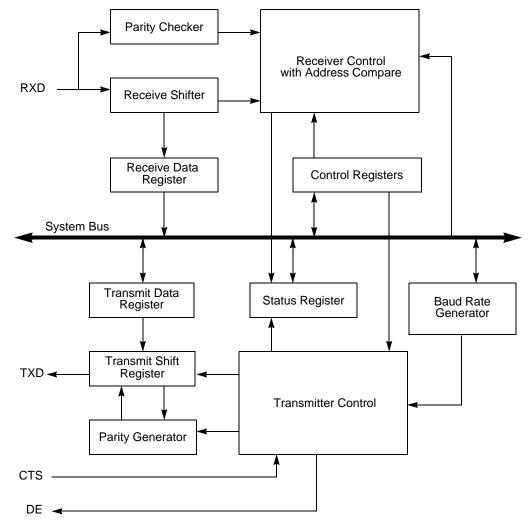

Watchdog Timer Control Register Definitions

This section defines the features of the following Watchdog Timer Control registers.

Watchdog Timer Control Register (WDTCTL): see page 94

Watchdog Timer Reload Upper Byte Register (WDTU): see page 95

Operation

The UART always transmits and receives data in an 8-bit data format, least-significant bit (lsb) first. An even or odd parity bit can be added to the data stream. Each character begins with an active Low Start bit and ends with either 1 or 2 active High Stop bits. Figure 11 and Figure 12 display the asynchronous data format employed by the UART without parity and with parity, respectively.

ilog[°] Embedded in Life An TIXYS Company

111

Bit	Description (Continued)
[2] TDRE	 Transmitter Data Register Empty This bit indicates that the UART Transmit Data Register is empty and ready for additional data. Writing to the UART Transmit Data Register resets this bit. 0 = Do not write to the UART Transmit Data Register. 1 = The UART Transmit Data Register is ready to receive an additional byte to be transmitted.
[1] TXE	Transmitter Empty This bit indicates that the transmit shift register is empty and character transmission is finished. 0 = Data is currently transmitting. 1 = Transmission is complete.
[0] CTS	CTS Signal When this bit is read, it returns the level of the $\overline{\text{CTS}}$ signal. This signal is active Low.

UART Status 1 Register

This register contains multiprocessor control and status bits.

Table 67. UART Stat	us 1 Register (U0STAT1)
---------------------	-------------------------

Bit	7	6	5	4	3	2	1	0

Address		F44H						

Bit	Description
[7:2]	Reserved These bits are reserved; R/W bits must be programmed to 000000 during writes and 000000 when read.
[1] NEWFRM	 New Frame A status bit denoting the start of a new frame. Reading the UART Receive Data Register resets this bit to 0. 0 = The current byte is not the first data byte of a new frame. 1 = The current byte is the first data byte of a new frame.
[0] MPRX	Multiprocessor Receive Returns the value of the most recent multiprocessor bit received. Reading from the UART Receive Data Register resets this bit to 0.

ilog Embedded in Life An∎IXYS Company 115

UART Address Compare Register

The UART Address Compare Register stores the multinode network address of the UART. When the MPMD[1] bit of UART Control Register 0 is set, all incoming address bytes are compared to the value stored in the Address Compare Register. Receive interrupts and RDA assertions only occur in the event of a match.

bits can only be set to 1. Thus, sectors can be protected, but not unprotected, via register write operations. Writing a value other than 5EH to the Flash Control Register deselects the Flash Sector Protect Register and reenables access to the Page Select Register.

Observe the following procedure to setup the Flash Sector Protect Register from user code:

- 1. Write 00H to the Flash Control Register to reset the Flash Controller.
- 2. Write 5EH to the Flash Control Register to select the Flash Sector Protect Register.
- 3. Read and/or write the Flash Sector Protect Register which is now at Register File address FF9H.
- 4. Write 00H to the Flash Control Register to return the Flash Controller to its reset state.

The Sector Protect Register is initialized to 0 on reset, putting each sector into an unprotected state. When a bit in the Sector Protect Register is written to 1, the corresponding sector can no longer be written or erased by the CPU. External Flash programming through the OCD or via the Flash Controller Bypass mode are unaffected. After a bit of the Sector Protect Register has been set, it cannot be cleared except by powering down the device.

Byte Programming

The Flash Memory is enabled for byte programming after unlocking the Flash Controller and successfully enabling either Mass Erase or Page Erase. When the Flash Controller is unlocked and Mass Erase is successfully completed, all Program Memory locations are available for byte programming. In contrast, when the Flash Controller is unlocked and Page Erase is successfully enabled, only the locations of the selected page are available for byte programming. An erased Flash byte contains all 1's (FFH). The programming operation can only be used to change bits from 1 to 0. To change a Flash bit (or multiple bits) from 0 to 1 requires execution of either the Page Erase or Mass Erase commands.

Byte Programming is accomplished using the On-Chip Debugger's Write Memory command or eZ8 CPU execution of the LDC or LDCI instructions. For a description of the LDC and LDCI instructions, refer to the <u>eZ8 CPU Core User Manual (UM0128)</u>, available for download at <u>www.zilog.com</u>. While the Flash Controller programs the Flash memory, the eZ8 CPU idles but the system clock and on-chip peripherals continue to operate. To exit programming mode and lock the Flash, write any value to the Flash Control Register, except the Mass Erase or Page Erase commands.

Caution: The byte at each address of the Flash memory cannot be programmed (any bits written to 0) more than twice before an erase cycle occurs. Doing so may result in corrupted data at the target byte.

Zilog Calibration Data

This section briefly describes the features of the following Flash Option Bit calibration registers.

ADC Calibration Data: see page 153

Serialization Data: see page 154

Randomized Lot Identifier: see page 154

 If the PA2/RESET pin is held Low while a 32-bit key sequence is issued to the PA0/ DBG pin, the DBG feature is unlocked. After releasing PA2/RESET, it is pulled high. At this point, the PA0/DBG pin can be used to autobaud and cause the device to enter DEBUG Mode. For more details, see the OCD Unlock Sequence (8-Pin Devices Only) section on page 161.

Exiting DEBUG Mode

The device exits DEBUG Mode following any of these operations:

- Clearing the DBGMODE bit in the OCD Control Register to 0
- Power-On Reset
- Voltage Brown-Out reset
- Watchdog Timer reset
- Asserting the **RESET** pin Low to initiate a Reset
- Driving the DBG pin Low while the device is in STOP Mode initiates a system reset

OCD Data Format

The OCD interface uses the asynchronous data format defined for RS-232. Each character is transmitted as 1 Start bit, 8 data bits (least-significant bit first), and 1 Stop bit as displayed in Figure 25.

	START	D0	D1	D2	D3	D4	D5	D6	D7	STOP	
--	-------	----	----	----	----	----	----	----	----	------	--

Figure 25. OCD Data Format

Note: When responding to a request for data, the OCD may commence transmitting immediately after receiving the stop bit of an incoming frame. Therefore, when sending the stop bit, the host must not actively drive the DBG pin High for more than 0.5 bit times. Zilog recommends that, if possible, the host drives the DBG pin using an open-drain output.

OCD Autobaud Detector/Generator

To run over a range of baud rates (data bits per second) with various system clock frequencies, the OCD contains an auto-baud detector/generator. After a reset, the OCD is idle until it receives data. The OCD requires that the first character sent from the host is the character 80H. The character 80H has eight continuous bits Low (one Start bit plus 7 data

Embedded in Life An IXYS Company

OCD Status Register

The OCD Status Register reports status information about the current state of the debugger and the system.

Table 103. OCD Status	Register (OCDSTAT)
-----------------------	--------------------

Bit	Description
[7] DBG	Debug Status 0 = NORMAL Mode. 1 = DEBUG Mode.
[6] HALT	HALT Mode 0 = Not in HALT Mode. 1 = In HALT Mode.
[5] FRPENB	Flash Read Protect Option Bit Enable 0 = FRP bit enabled to allow disabling of many OCD commands. 1 = FRP bit has no effect.
[4:0]	Reserved These bits are reserved and must be 00000 when read.

Assembly Language Source Program Example

JP START	; Everything after the semicolon is a comment.
START:	; A label called 'START'. The first instruction (JP START) in this ; example causes program execution to jump to the point within the ; program where the START label occurs.
LD R4, R7	; A Load (LD) instruction with two operands. The first operand, ; Working Register R4, is the destination. The second operand, ; Working Register R7, is the source. The contents of R7 is ; written into R4.
LD 234H, #%01	; Another Load (LD) instruction with two operands. ; The first operand, Extended Mode Register Address 234H, ; identifies the destination. The second operand, Immediate Data ; value 01H, is the source. The value 01H is written into the ; Register at address 234H.

Assembly Language Syntax

For proper instruction execution, eZ8 CPU assembly language syntax requires that the operands be written as 'destination, source'. After assembly, the object code usually has the operands in the order 'source, destination', but ordering is opcode-dependent. The following instruction examples illustrate the format of some basic assembly instructions and the resulting object code produced by the assembler. You must follow this binary format if you prefer manual program coding or intend to implement your own assembler.

Example 1

If the contents of registers 43H and 08H are added and the result is stored in 43H, the assembly syntax and resulting object code is shown in Table 106.

Table 106. Assembly Language Syntax Example 1

Assembly Language Code	ADD	43H,	08H	(ADD dst, src)
Object Code	04	08	43	(OPC src, dst)

Example 2

In general, when an instruction format requires an 8-bit register address, that address can specify any register location in the range 0–255 or, using Escaped Mode Addressing, a Working Register R0–R15. If the contents of Register 43H and Working Register R8 are added and the result is stored in 43H, the assembly syntax and resulting object code is shown in Table 107.

Table 118. eZ8 CPU Instruction Summary (Continued)

Note: Flags Notation:

* = Value is a function of the result of the operation.

- = Unaffected.

X = Undefined.

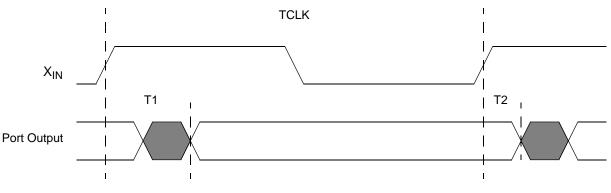

0 = Reset to 0.

1 = Set to 1.

ilog[°] Embedded in Life An IXYS Company 206

General Purpose I/O Port Output Timing

Figure 30 and Table 131 provide timing information for GPIO Port pins.

		Delay (ns)			
Parameter	Abbreviation	Minimum	Maximum		
GPIO Port p	bins				
T ₁	X _{IN} Rise to Port Output Valid Delay	_	15		
T ₂	X _{IN} Rise to Port Output Hold Time	2	_		

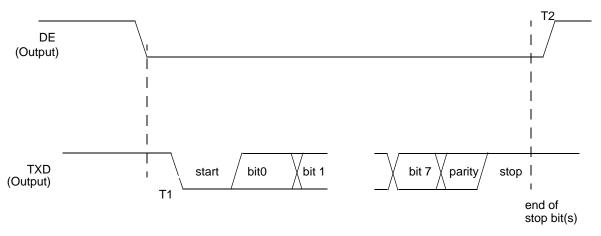

Table 131. GPIO Port Output Timing

209

0g

■IXYS Company

Figure 33 and Table 134 provide timing information for UART pins for the case where CTS is not used for flow control. DE asserts after the transmit data register has been written. DE remains asserted for multiple characters as long as the transmit data register is written with the next character before the current character has completed.

		Delay (ns)					
Parameter	Abbreviation	Minimum	Maximum				
UART							
T ₁	DE assertion to TXD falling edge (start bit) delay	1 * X _{IN} period	1 bit time				
T ₂	End of Stop Bit(s) to DE deassertion delay (Tx data register is empty)	± 5
