What is "Embedded - Microcontrollers"?

"Embedded - Microcontrollers" refer to small, integrated circuits designed to perform specific tasks within larger systems. These microcontrollers are essentially compact computers on a single chip, containing a processor core, memory, and programmable input/output peripherals. They are called "embedded" because they are embedded within electronic devices to control various functions, rather than serving as standalone computers. Microcontrollers are crucial in modern electronics, providing the intelligence and control needed for a wide range of applications.

4.3 Voltage regulator electrical characteristics

The voltage regulator is composed of the following blocks:

- Choice of generating supply voltage for the core area.
    - Control of external NPN ballast transistor
    - Generating core supply using internal ballast transistor
    - Connecting an external 1.25 V (nominal) supply directly without the NPN ballast
- Internal generation of the 3.3 V flash supply when device connected in 5V applications
- External bypass of the 3.3 V flash regulator when device connected in 3.3V applications
- Low voltage detector - low threshold (LVD_IO_A_LO) for $V_{DD\_HV\_IO\_A\ supply}$
- Low voltage detector - high threshold (LVD_IO_A_Hi) for $V_{DD\_HV\_IO\_A\ supply}$
- Low voltage detector (LVD_FLASH) for 3.3 V flash supply (VDD_HV_FLA)
- Various low voltage detectors (LVD_LV_x)
- High voltage detector (HVD_LV_cold) for 1.2 V digital core supply (VDD_LV)
- Power on Reset (POR_LV) for 1.25 V digital core supply (VDD_LV)
- Power on Reset (POR_HV) for 3.3 V to 5 V supply (VDD_HV_A)

The following bipolar transistors[1] are supported, depending on the device performance requirements. As a minimum the following must be considered when determining the most appropriate solution to maintain the device under its maximum power dissipation capability: current, ambient temperature, mounting pad area, duty cycle and frequency for Idd, collector voltage, etc

4.6 Electrostatic discharge (ESD) characteristics

Electrostatic discharges (a positive then a negative pulse separated by 1 second) are applied to the pins of each sample according to each pin combination. The sample size depends on the number of supply pins in the device (3 parts × (n + 1) supply pin). This test conforms to the AEC-Q100-002/-003/-011 standard.

NOTE

A device will be defined as a failure if after exposure to ESD pulses the device no longer meets the device specification requirements. Complete DC parametric and functional testing shall be performed per applicable device specification at room temperature followed by hot temperature, unless specified otherwise in the device specification.

10.1.2 BAF execution duration

Following table specifies the typical BAF execution time in case BAF boot header is present at first location (Typical) and last location (worst case). Total Boot time is the sum of reset sequence duration and BAF execution time.

Table 50. BAF execution duration

BAF execution duration	Min	Typ	Max	Unit
BAF execution time (boot header at first location)	—	200	—	µs
BAF execution time (boot header at last location)	—	—	320	µs

10.1.3 Reset sequence description

The figures in this section show the internal states of the device during the five different reset sequences. The dotted lines in the figures indicate the starting point and the end point for which the duration is specified in .

With the beginning of DRUN mode, the first instruction is fetched and executed. At this point, application execution starts and the internal reset sequence is finished.

The following figures show the internal states of the device during the execution of the reset sequence and the possible states of the RESET_B signal pin.

NOTE

RESET_B is a bidirectional pin. The voltage level on this pin can either be driven low by an external reset generator or by the device internal reset circuitry. A high level on this pin can only be generated by an external pullup resistor which is strong enough to overdrive the weak internal pulldown resistor. The rising edge on RESET_B in the following figures indicates the time when the device stops driving it low. The reset sequence durations given in are applicable only if the internal reset sequence is not prolonged by an external reset generator keeping RESET_B asserted low beyond the last Phase3.
