What is "Embedded - Microcontrollers"?

"Embedded - Microcontrollers" refer to small, integrated circuits designed to perform specific tasks within larger systems. These microcontrollers are essentially compact computers on a single chip, containing a processor core, memory, and programmable input/output peripherals. They are called "embedded" because they are embedded within electronic devices to control various functions, rather than serving as standalone computers. Microcontrollers are crucial in modern electronics, providing the intelligence and control needed for a wide range of applications.

4.2 Recommended operating conditions

The following table describes the operating conditions for the device, and for which all specifications in the data sheet are valid, except where explicitly noted. The device operating conditions must not be exceeded in order to guarantee proper operation and reliability. The ranges in this table are design targets and actual data may vary in the given range.

NOTE

- For normal device operations, all supplies must be within operating range corresponding to the range mentioned in following tables. This is required even if some of the features are not used.
- If VDD_HV_A is in 3.3V range, VDD_HV_FLA should be externally supplied using a 3.3V source. If VDD_HV_A is in 3.3V range, VDD_HV_FLA should be shorted to VDD_HV_A.
- VDD_HV_A, VDD_HV_B and VDD_HV_C are all independent supplies and can each be set to 3.3V or 5V. The following tables: 'Recommended operating conditions (VDD_HV_x = 3.3 V)' and table 'Recommended operating conditions (VDD_HV_x = 5 V)' specify their ranges when configured in 3.3V or 5V respectively.

4.6 Electrostatic discharge (ESD) characteristics

Electrostatic discharges (a positive then a negative pulse separated by 1 second) are applied to the pins of each sample according to each pin combination. The sample size depends on the number of supply pins in the device (3 parts × (n + 1) supply pin). This test conforms to the AEC-Q100-002/-003/-011 standard.

NOTE

A device will be defined as a failure if after exposure to ESD pulses the device no longer meets the device specification requirements. Complete DC parametric and functional testing shall be performed per applicable device specification at room temperature followed by hot temperature, unless specified otherwise in the device specification.

6.2 Clocks and PLL interfaces modules

6.2.1 Main oscillator electrical characteristics

This device provides a driver for oscillator in pierce configuration with amplitude control. Controlling the amplitude allows a more sinusoidal oscillation, reducing in this way the EMI. Other benefits arises by reducing the power consumption. This Loop Controlled Pierce (LCP mode) requires good practices to reduce the stray capacitance of traces between crystal and MCU.

An operation in Full Swing Pierce (FSP mode), implemented by an inverter is also available in case of parasitic capacitances and cannot be reduced by using crystal with high equivalent series resistance. For this mode, a special care needs to be taken regarding the serial resistance used to avoid the crystal overdrive.

Other two modes called External (EXT Wave) and disable (OFF mode) are provided. For EXT Wave, the drive is disabled and an external source of clock within CMOS level based in analog oscillator supply can be used. When OFF, EXTAL is pulled down by 240 Kohms resistor and the feedback resistor remains active connecting XTAL through EXTAL by 1M resistor.

Table 31. Flash memory Array Integrity and Margin Read specifications (continued)

Symbol	Characteristic	Min	Typical	Max[1, 1]	Units[2, 2]
$t_{ai256kseq}$	Array Integrity time for sequential sequence on 256 KB block.	—	—	8192 x Tperiod x Nread	—
$t_{mr16kseq}$	Margin Read time for sequential sequence on 16 KB block.	73.81	—	110.7	µs
$t_{mr32kseq}$	Margin Read time for sequential sequence on 32 KB block.	128.43	—	192.6	µs
$t_{mr64kseq}$	Margin Read time for sequential sequence on 64 KB block.	237.65	—	356.5	µs
$t_{mr256kseq}$	Margin Read time for sequential sequence on 256 KB block.	893.01	—	1,339.5	µs

1. Array Integrity times need to be calculated and is dependent on system frequency and number of clocks per read. The equation presented require Tperiod (which is the unit accurate period, thus for 200 MHz, Tperiod would equal 5e-9) and Nread (which is the number of clocks required for read, including pipeline contribution. Thus for a read setup that requires 6 clocks to read with no pipeline, Nread would equal 6. For a read setup that requires 6 clocks to read, and has the address pipeline set to 2, Nread would equal 4 (or 6 - 2).)
2. The units for Array Integrity are determined by the period of the system clock. If unit accurate period is used in the equation, the results of the equation are also unit accurate.

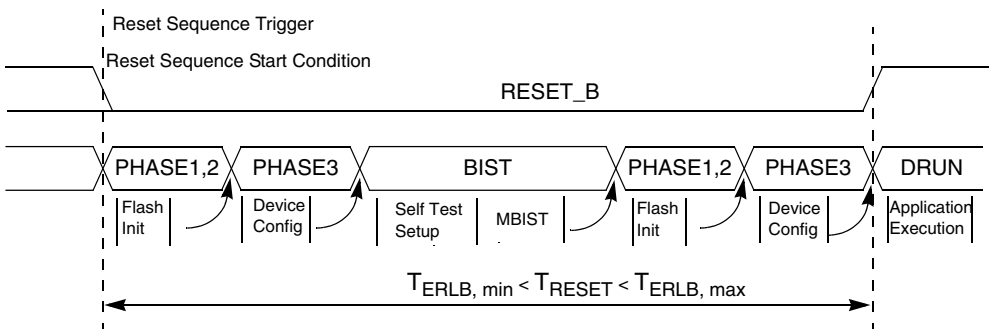

Figure 34. External reset sequence long, BIST enabled

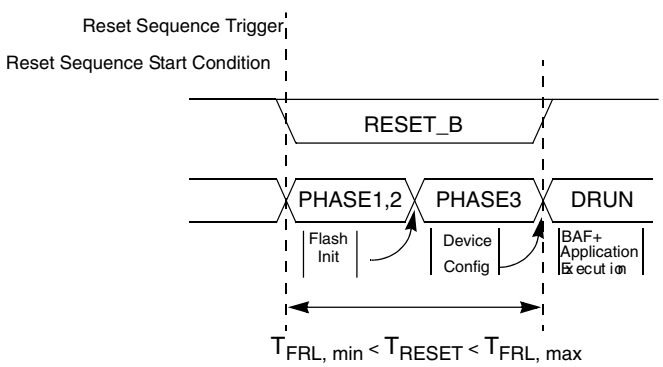

Figure 35. Functional reset sequence long

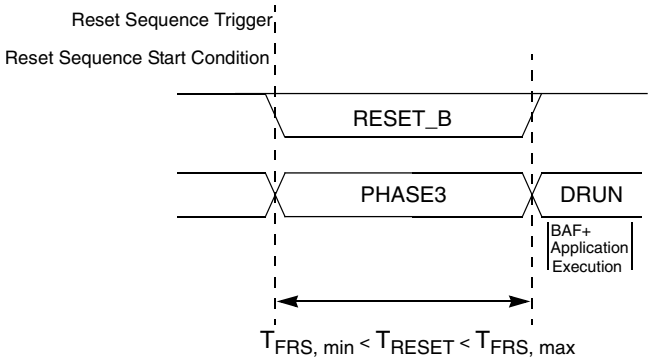

Figure 36. Functional reset sequence short

The reset sequences shown in Figure 35 and Figure 36 are triggered by functional reset events. RESET_B is driven low during these two reset sequences only if the corresponding functional reset source (which triggered the reset sequence) was enabled to drive RESET_B low for the duration of the internal reset sequence. See the RGM_FBRE register in the device reference manual for more information.
