
Welcome to E-XFL.COM

What is "Embedded - Microcontrollers"?

"Embedded - Microcontrollers" refer to small, integrated circuits designed to perform specific tasks within larger systems. These microcontrollers are essentially compact computers on a single chip, containing a processor core, memory, and programmable input/output peripherals. They are called "embedded" because they are embedded within electronic devices to control various functions, rather than serving as standalone computers. Microcontrollers are crucial in modern electronics, providing the intelligence and control needed for a wide range of applications.

Applications of "Embedded - Microcontrollers"

Details	
Product Status	Obsolete
Core Processor	dsPIC
Core Size	16-Bit
Speed	20 MIPS
Connectivity	CANbus, I²C, SPI, UART/USART
Peripherals	Brown-out Detect/Reset, LVD, Motor Control PWM, QEI, POR, PWM, WDT
Number of I/O	52
Program Memory Size	144KB (48K x 24)
Program Memory Type	FLASH
EEPROM Size	4K x 8
RAM Size	8K x 8
Voltage - Supply (Vcc/Vdd)	2.5V ~ 5.5V
Data Converters	A/D 16x10b
Oscillator Type	Internal
Operating Temperature	-40°C ~ 125°C (TA)
Mounting Type	Surface Mount
Package / Case	64-TQFP
Supplier Device Package	64-TQFP (10x10)
Purchase URL	https://www.e-xfl.com/product-detail/microchip-technology/dspic30f6015t-20e-pt

5.0 DEVICE PROGRAMMING

5.1 Overview of the Programming Process

Once the programming executive has been verified in memory (or loaded if not present), the dsPIC30F can be programmed using the command set shown in Table 5-1. A detailed description for each command is provided in **Section 8.0 "Programming Executive Commands"**.

TABLE 5-1: COMMAND SET SUMMARY

Command	Description
SCHECK	Sanity check
READD	Read data EEPROM, Configuration registers and device ID
READP	Read code memory
PROGD	Program one row of data EEPROM and verify
PROGP	Program one row of code memory and verify
PROGC	Program Configuration bits and verify
ERASEB	Bulk Erase, or erase by segment
ERASED	Erase data EEPROM
ERASEP	Erase code memory
QBLANK	Query if the code memory and data EEPROM are blank
QVER	Query the software version

A high-level overview of the programming process is illustrated in Figure 5-1. The process begins by entering Enhanced ICSP mode. The chip is then bulk erased, which clears all memory to '1' and allows the device to be programmed. The Chip Erase is verified before programming begins. Next, the code memory, data Flash and Configuration bits are programmed. As these memories are programmed, they are each verified to ensure that programming was successful. If no errors are detected, the programming is complete and Enhanced ICSP mode is exited. If any of the verifications fail, the procedure should be repeated, starting from the Chip Erase.

If Advanced Security features are enabled, then individual Segment Erase operations need to be performed, based on user selections (i.e., based on the specific needs of the user application). The specific operations that are used typically depend on the order in which various segments need to be programmed for a given application or system.

Section 5.2 "Entering Enhanced ICSP Mode" through **Section 5.8 "Exiting Enhanced ICSP Mode"** describe the programming process in detail.

8.0 PROGRAMMING EXECUTIVE COMMANDS

8.1 Command Set

The programming executive command set is shown in Table 8-1. This table contains the opcode, mnemonic, length, time out and description for each command. Functional details on each command are provided in the command descriptions (see **Section 8.5 "Command Descriptions"**).

8.2 Command Format

All programming executive commands have a general format consisting of a 16-bit header and any required data for the command (see Figure 8-1). The 16-bit header consists of a 4-bit opcode field, which is used to identify the command, followed by a 12-bit command length field.

FIGURE 8-1: COMMAND FORMAT

15 12	11 0
Opcode	Length
Command Data First Word (if required)	
•	
•	
Command Data Last Word (if required)	

The command opcode must match one of those in the command set. Any command that is received which does not match the list in Table 8-1 will return a "NACK" response (see **Section 9.2.1 "Opcode Field"**).

The command length is represented in 16-bit words since the SPI operates in 16-bit mode. The programming executive uses the Command Length field to determine the number of words to read from the SPI port. If the value of this field is incorrect, the command will not be properly received by the programming executive.

8.3 Packed Data Format

When 24-bit instruction words are transferred across the 16-bit SPI interface, they are packed to conserve space using the format shown in Figure 8-2. This format minimizes traffic over the SPI and provides the programming executive with data that is properly aligned for performing table write operations.

FIGURE 8-2: PACKED INSTRUCTION WORD FORMAT

15 8	7 0
lsw1	
MSB2	MSB1
lsw2	

lswx: Least significant 16 bits of instruction word
MSBx: Most Significant Byte of instruction word

Note:	When the number of instruction words transferred is odd, MSB2 is zero and lsw2 cannot be transmitted.

8.4 Programming Executive Error Handling

The programming executive will "NACK" all unsupported commands. Additionally, due to the memory constraints of the programming executive, no checking is performed on the data contained in the Programmer command. It is the responsibility of the programmer to command the programming executive with valid command arguments, or the programming operation may fail. Additional information on error handling is provided in **Section 9.2.3 "QE_Code Field"**.

8.5 Command Descriptions

All commands that are supported by the programming executive are described in **Section 8.5.1 "SCHECK Command"** through **Section 8.5.11 "QVER Command"**.

8.5.1 SCHECK COMMAND

15 12	11 0
Opcode	Length

Field	Description
Opcode	0x0
Length	0x1

The SCHECK command instructs the programming executive to do nothing, but generate a response. This command is used as a "sanity check" to verify that the programming executive is operational.

Expected Response (2 words):
0x1000
0x0002

Note:	This instruction is not required for programming, but is provided for development purposes only.

8.5.2 READD COMMAND

15 12	11 8	7 0
Opcode	Length	
Reserved0	N	
Reserved1		Addr_MSB
Addr_LS		

Field	Description
Opcode	0x1
Length	0x4
Reserved0	0x0
N	Number of 16-bit words to read (max of 2048)
Reserved1	0x0
Addr_MSB	MSB of 24-bit source address
Addr_LS	LS 16 bits of 24-bit source address

The READD command instructs the programming executive to read N 16-bit words of memory starting from the 24-bit address specified by Addr_MSB and Addr_LS. This command can only be used to read 16-bit data. It can be used to read data EEPROM, Configuration registers and the device ID.

Expected Response (2+N words):
0x1100
N + 2
Data word 1
...
Data word N

Note:	Reading unimplemented memory will cause the programming executive to reset.

8.5.3 READP COMMAND

15 12	11 8	7 0
Opcode	Length	
N		
Reserved	Addr_MSB	
Addr_LS		

Field	Description
Opcode	0x2
Length	0x4
N	Number of 24-bit instructions to read (max of 32768)
Reserved	0x0
Addr_MSB	MSB of 24-bit source address
Addr_LS	LS 16 bits of 24-bit source address

The READP command instructs the programming executive to read N 24-bit words of code memory starting from the 24-bit address specified by Addr_MSB and Addr_LS. This command can only be used to read 24-bit data. All data returned in response to this command uses the packed data format described in **Section 8.3 "Packed Data Format"**.

Expected Response (2 + 3 * N/2 words for N even):
0x1200
2 + 3 * N/2
Least significant program memory word 1
...
Least significant data word N

Expected Response (4 + 3 * (N – 1)/2 words for N odd):
0x1200
4 + 3 * (N – 1)/2
Least significant program memory word 1
...
MSB of program memory word N (zero padded)

Note:	Reading unimplemented memory will cause the programming executive to reset.

8.5.4 PROGD COMMAND

15 12	11 8	7 0
Opcode	Length	
Reserved	Addr_MSB	
Addr_LS		
D_1		
D_2		
...		
D_16		

Field	Description
Opcode	0x4
Length	0x13
Reserved	0x0
Addr_MSB	MSB of 24-bit destination address
Addr_LS	LS 16 bits of 24-bit destination address
D_1	16-bit data word 1
D_2	16-bit data word 2
...	16-bit data words 3 through 15
D_16	16-bit data word 16

The PROGD command instructs the programming executive to program one row of data EEPROM. The data to be programmed is specified by the 16 data words (D_1, D_2,..., D_16) and is programmed to the destination address specified by Addr_MSB and Addr_LSB. The destination address should be a multiple of 0x20.

Once the row of data EEPROM has been programmed, the programming executive verifies the programmed data against the data in the command.

Expected Response (2 words):
0x1400
0x0002

Note:	Refer to Table 5-3 for data EEPROM size information.

8.5.11 QVER COMMAND

15 12	11 0
Opcode	Length

Field	Description
Opcode	0xB
Length	0x1

The QVER command queries the version of the programming executive software stored in test memory. The “version.revision” information is returned in the response’s QE_Code using a single byte with the following format: main version in upper nibble and revision in the lower nibble (i.e., 0x23 is version 2.3 of programming executive software).

Expected Response (2 words):
0x1BMN (where “MN” stands for version M.N)
0x0002

9.0 PROGRAMMING EXECUTIVE RESPONSES

9.1 Overview

The programming executive sends a response to the programmer for each command that it receives. The response indicates if the command was processed correctly, and includes any required response or error data.

The programming executive response set is shown in Table 9-1. This table contains the opcode, mnemonic and description for each response. The response format is described in **Section 9.2 “Response Format”**.

TABLE 9-1: PROGRAMMING EXECUTIVE RESPONSE SET

Opcode	Mnemonic	Description
0x1	PASS	Command successfully processed.
0x2	FAIL	Command unsuccessfully processed.
0x3	NACK	Command not known.

9.2 Response Format

As shown in Example 9-1, all programming executive responses have a general format consisting of a two word header and any required data for the command. Table 9-2 lists the fields and their descriptions.

EXAMPLE 9-1: FORMAT

15 12	11 8	7 0
Opcode	Last_Cmd	QE_Code
Length		
D_1 (if applicable)		
...		
D_N (if applicable)		

TABLE 9-2: FIELDS AND DESCRIPTIONS

Field	Description
Opcode	Response opcode.
Last_Cmd	Programmer command that generated the response.
QE_Code	Query code or Error code.
Length	Response length in 16-bit words (includes 2 header words.)
D_1	First 16-bit data word (if applicable).
D_N	Last 16-bit data word (if applicable).

9.2.1 Opcode FIELD

The Opcode is a 4-bit field in the first word of the response. The Opcode indicates how the command was processed (see Table 9-1). If the command is processed successfully, the response opcode is PASS. If there is an error in processing the command, the response opcode is FAIL, and the QE_Code indicates the reason for the failure. If the command sent to the programming executive is not identified, the programming executive returns a NACK response.

9.2.2 Last_Cmd FIELD

The Last_Cmd is a 4-bit field in the first word of the response and indicates the command that the programming executive processed. Since the programming executive can only process one command at a time, this field is technically not required. However, it can be used to verify whether the programming executive correctly received the command that the programmer transmitted.

TABLE 10-3: DEVICE ID BITS DESCRIPTION

Bit Field	Register	Description
DEVID<15:0>	DEVID	Encodes the device ID.
PROC<3:0>	DEVREV	Encodes the process of the device (always read as 0x001).
REV<5:0>	DEVREV	Encodes the major revision number of the device. 000000 = A 000001 = B 000010 = C
DOT<5:0>	DEVREV	Encodes the minor revision number of the device. 000000 = 0 000001 = 1 000010 = 2 000011 = 3
Examples: Rev A.1 = 0000 0000 0000 0001 Rev A.2 = 0000 0000 0000 0010 Rev B.0 = 0000 0000 0100 0000 This formula applies to all dsPIC30F devices, with the exception of the following: • dsPIC30F6010 • dsPIC30F6011 • dsPIC30F6012 • dsPIC30F6013 • dsPIC30F6014 Refer to Table 10-1 for the actual revision IDs.		

11.7 Writing Configuration Memory

The FOSC, FWDT, FBORPOR and FICD registers are not erasable. It is recommended that all Configuration registers be set to a default value after erasing program memory. The FWDT, FBORPOR and FICD registers can be set to a default all '1's value by programming 0xFFFF to each register. Since these registers contain unimplemented bits that read as '0' the default values shown in Table 11-6 will be read instead of 0xFFFF. The recommended default FOSC value is 0xC100, which selects the FRC clock oscillator setting.

The FGS, FBS and FSS Configuration registers are special since they enable code protection for the device. For security purposes, once any bit in these registers is programmed to '0' (to enable some code protection feature), it can only be set back to '1' by performing a Bulk Erase or Segment Erase as described in **Section 11.5 "Erasing Program Memory in Normal-Voltage Systems"**. Programming these bits from a '0' to '1' is not possible, but they may be programmed from a '1' to a '0' to enable code protection.

Table 11-7 shows the ICSP programming details for clearing the Configuration registers. In Step 1, the Reset vector is exited. In Step 2, the write pointer (W7) is loaded with 0x0000, which is the original destination address (in TBLPAG 0xF8 of program memory). In Step 3, the NVMCON is set to program one Configuration register. In Step 4, the TBLPAG register is initialized, to 0xF8, for writing to the Configuration registers. In Step 5, the value to write to the each Configuration register (0xFFFF) is loaded to W6. In Step 6, the Configuration register data is written to the write latch using the TBLWTL instruction. In Steps 7 and 8, the NVMCON is unlocked for programming and the programming cycle is initiated, as described in **Section 11.4 "Flash Memory Programming in ICSP Mode"**. In Step 9, the internal PC is set to 0x100 as a safety measure to prevent the PC from incrementing into unimplemented memory. Lastly, Steps 3-9 are repeated six times until all seven Configuration registers are cleared.

TABLE 11-6: DEFAULT CONFIGURATION REGISTER VALUES

Address	Register	Default Value
0xF80000	FOSC	0xC100
0xF80002	FWDT	0x803F
0xF80004	FBORPOR	0x87B3
0xF80006	FBS	0x310F
0xF80008	FSS	0x330F
0xF8000A	FGS	0x0007
0xF8000C	FICD	0xC003

TABLE 11-7: SERIAL INSTRUCTION EXECUTION FOR WRITING CONFIGURATION REGISTERS

Command (Binary)	Data (Hexadecimal)	Description
Step 1: Exit the Reset vector.		
0000 0000 0000	040100 040100 000000	GOTO 0x100 GOTO 0x100 NOP
Step 2: Initialize the write pointer (W7) for the TBLWT instruction.		
0000	200007	MOV #0x0000, W7
Step 3: Set the NVMCON to program 1 Configuration register.		
0000 0000	24008A 883B0A	MOV #0x4008, W10 MOV W10, NVMCON
Step 4: Initialize the TBLPAG register.		
0000 0000	200F80 880190	MOV #0xF8, W0 MOV W0, TBLPAG
Step 5: Load the Configuration register data to W6.		
0000 0000	2xxxx0 000000	MOV #<CONFIG_VALUE>, W0 NOP

11.8 Writing Code Memory

The procedure for writing code memory is similar to the procedure for clearing the Configuration registers, except that 32 instruction words are programmed at a time. To facilitate this operation, working registers W0:W5 are used as temporary holding registers for the data to be programmed.

Table 11-8 shows the ICSP programming details, including the serial pattern with the ICSP command code, which must be transmitted Least Significant bit first using the PGC and PGD pins (see Figure 11-2). In Step 1, the Reset vector is exited. In Step 2, the NVMCON register is initialized for single-panel programming of code memory. In Step 3, the 24-bit starting destination address for programming is loaded into the TBLPAG register and W7 register. The upper byte of the starting destination address is stored to TBLPAG, while the lower 16 bits of the destination address are stored to W7.

To minimize the programming time, the same packed instruction format that the programming executive uses is utilized (Figure 8-2). In Step 4, four packed instruction words are stored to working registers W0:W5 using the `MOV` instruction and the read pointer W6 is initialized. The contents of W0:W5 holding the packed instruction word data is shown in Figure 11-4.

In Step 5, eight `TBLWT` instructions are used to copy the data from W0:W5 to the write latches of code memory. Since code memory is programmed 32 instruction words at a time, Steps 4 and 5 are repeated eight times to load all the write latches (Step 6).

After the write latches are loaded, programming is initiated by writing to the NVMKEY and NVMCON registers in Steps 7 and 8. In Step 9, the internal PC is reset to 0x100. This is a precautionary measure to prevent the PC from incrementing into unimplemented memory when large devices are being programmed. Lastly, in Step 10, Steps 2-9 are repeated until all of code memory is programmed.

FIGURE 11-5: PACKED INSTRUCTION WORDS IN W0:W5

		MOV #<LSW3>, W5

11.10 Reading Code Memory

Reading from code memory is performed by executing a series of TBLRD instructions and clocking out the data using the REGOUT command. To ensure efficient execution and facilitate verification on the programmer, four instruction words are read from the device at a time.

Table 11-10 shows the ICSP programming details for reading code memory. In Step 1, the Reset vector is exited. In Step 2, the 24-bit starting source address for reading is loaded into the TBLPAG and W6 registers. The upper byte of the starting source address is stored to TBLPAG, while the lower 16 bits of the source address are stored to W6.

To minimize the reading time, the packed instruction word format that was utilized for writing is also used for reading (see Figure 11-5). In Step 3, the write pointer W7 is initialized, and four instruction words are read from code memory and stored to working registers W0:W5. In Step 4, the four instruction words are clocked out of the device from the VISI register using the REGOUT command. In Step 5, the internal PC is reset to 0x100, as a precautionary measure, to prevent the PC from incrementing into unimplemented memory when large devices are being read. Lastly, in Step 6, Steps 3-5 are repeated until the desired amount of code memory is read.

TABLE 11-10: SERIAL INSTRUCTION EXECUTION FOR READING CODE MEMORY

Command (Binary)	Data (Hexadecimal)	Description
Step 1: Exit the Reset vector.		
0000	040100	GOTO 0x100

0000	000000	NOP
Step 5: Reset the device internal PC.		
0000	040100	GOTO 0x100
0000	000000	NOP
Step 6: Repeat steps 3-5 until all desired code memory is read.		

11.12 Reading Data Memory

The procedure for reading data memory is similar to that of reading code memory, except that 16-bit data words are read instead of 24-bit words. Since less data is read in each operation, only working registers W0:W3 are used as temporary holding registers for the data to be read.

Table 11-12 shows the ICSP programming details for reading data memory. Note that the TBLPAG register is hard-coded to 0x7F (the upper byte address of all locations of data memory).

TABLE 11-12: SERIAL INSTRUCTION EXECUTION FOR READING DATA MEMORY

Command (Binary)	Data (Hexadecimal)	Description
Step 1: Exit the Reset vector.		
0000	040100	GOTO 0x100
0000	040100	GOTO 0x100
0000	000000	NOP
Step 2: Initialize TBLPAG and the read pointer (W6) for TBLRD instruction.		
0000	2007F0	MOV #0x7F, W0
0000	880190	MOV W0, TBLPAG
0000	2xxxx6	MOV #<SourceAddress15:0>, W6
Step 3: Initialize the write pointer (W7) and store the next four locations of code memory to W0:W5.

Item Description:

SUM(a:b) = Byte sum of locations a to b inclusive (all 3 bytes of code memory)

CFGB = **Configuration Block (masked)** = Byte sum of ((FOSC&0xC10F) + (FWDT&0x803F) + (FBORPOR&0x87B3) + (FBS&0x310F) + (FSS&0x330F) + (FGS&0x0007) + (FICD&0xC003))

APPENDIX B: HEX FILE FORMAT

Flash programmers process the standard HEX format used by the Microchip development tools. The format supported is the Intel® HEX 32 Format (INHX32). Please refer to Appendix A in the "*MPASM User's Guide"* (DS33014) for more information about hex file formats.

The basic format of the hex file is:

```
:BBAAAATTHHHH...HHHHCC
```

Each data record begins with a 9-character prefix and always ends with a 2-character checksum. All records begin with '`:`' regardless of the format. The individual elements are described below.

- `BB` - is a two-digit hexadecimal byte count representing the number of data bytes that appear on the line. Divide this number by two to get the number of words per line.
- `AAAA` - is a four-digit hexadecimal address representing the starting address of the data record. Format is high byte first followed by low byte. The address is doubled because this format only supports 8-bits. Divide the value by two to find the real device address.
- `TT` - is a two-digit record type that will be '00' for data records, '01' for end-of-file records and '04' for extended-address record.
- `HHHH` - is a four-digit hexadecimal data word. Format is low byte followed by high byte. There will be `BB`/2 data words following `TT`.
- `CC` - is a two-digit hexadecimal checksum that is the two's complement of the sum of all the preceding bytes in the line record.

Because the Intel hex file format is byte-oriented, and the 16-bit program counter is not, program memory sections require special treatment. Each 24-bit program word is extended to 32 bits by inserting a so-called "phantom byte". Each program memory address is multiplied by 2 to yield a byte address.

As an example, a section that is located at 0x100 in program memory will be represented in the hex file as 0x200.

The hex file will be produced with the following contents:

```
:020000040000fa
:040200003322110096
:00000001FF
```

Notice that the data record (line 2) has a load address of 0200, while the source code specified address 0x100. Note also that the data is represented in "little-endian" format, meaning the Least Significant Byte (LSB) appears first. The phantom byte appears last, just before the checksum.

NOTES:
