What is "Embedded - Microcontrollers"?

"Embedded - Microcontrollers" refer to small, integrated circuits designed to perform specific tasks within larger systems. These microcontrollers are essentially compact computers on a single chip, containing a processor core, memory, and programmable input/output peripherals. They are called "embedded" because they are embedded within electronic devices to control various functions, rather than serving as standalone computers. Microcontrollers are crucial in modern electronics, providing the intelligence and control needed for a wide range of applications.

4.6.5. I2C (I2C0, I2C1)

The I2C interface is a two-wire, bi-directional serial bus. The two clock and data signals operate in open-drain mode with external pull-ups to support automatic bus arbitration.

Reads and writes to the interface are byte oriented with the I2C interface autonomously controlling the serial transfer of the data. Data can be transferred at up to 1/8th of the APB clock as a master or slave, which can be faster than allowed by the I2C specification, depending on the clock source used. A method of extending the clock-low duration is available to accommodate devices with different speed capabilities on the same bus.

The I2C interface may operate as a master and/or slave, and may function on a bus with multiple masters. The I2C provides control of SDA (serial data), SCL (serial clock) generation and synchronization, arbitration logic, and start/stop control and generation.

The I2C module includes the following features:

- Standard (up to 100 kbps) and Fast (400 kbps) transfer speeds.
- Can operate down to APB clock divided by 32768 or up to APB clock divided by 8.

4.7. Analog

4.7.1. 12-Bit Analog-to-Digital Converters (SARADC0, SARADC1)

The SARADC0 and SARADC1 modules on SiM3C1xx devices are Successive Approximation Register (SAR) Analog to Digital Converters (ADCs). The key features of the SARADC module are:

- Flexible output data formatting.
- Sequencer allows up to 8 sources to be automatically scanned using one of four channel characteristic profiles without software intervention.
- Eight-word conversion data FIFO for DMA operations.
- Multiple SARADC modules can work together synchronously or by interleaving samples.

4.7.2. Sample Sync Generator (SSG0)

The SSG module includes a phase counter and a pulse generator. The phase counter is a 4-bit free-running counter clocked from the SARADC module clock. Counting-up from zero, the phase counter marks sixteen equally-spaced events for any number of SARADC modules. The ADCs can use this phase counter to start a conversion. The programmable pulse generator creates a 50% duty cycle pulse with a period of 16 phase counter ticks. Up to four programmable outputs available to external devices can be driven by the pulse generator with programmable polarity and a defined output setting when the pulse generator is stopped.

The Sample Sync Generator module has the following features:

- Connects multiple modules together to perform synchronized actions.
- Outputs a clock synchronized to the internal sampling clock used by any number of SARADC modules to pins for use by external devices.
- Includes a phase counter, pulse generator, and up to four programmable outputs.

4.7.3. 10-Bit Digital-to-Analog Converter (IDAC0, IDAC1)

The IDAC takes a digital value as an input and outputs a proportional constant current on a pin. The IDAC module includes the following features:

- 10-bit current DAC with support for four timer, up to seven external I/O, on demand, and SSG0 output update triggers.
- Ability to update on rising, falling, or both edges for any of the external I/O trigger sources (DACnTx).
- Supports an output update rate greater than 600 k samples per second.
- Support for three full-scale output modes: 0.5 mA, 1.0 mA and 2.0 mA.
- Four-word FIFO to aid with high-speed waveform generation or DMA interactions.
- Individual FIFO overrun, underrun, and went-empty interrupt status sources.
- Support for multiple data packing formats, including: single 10-bit sample per word, dual 10-bit samples per word, or four 8-bit samples per word.
- Support for left- and right-justified data.

4.8. Reset Sources

Reset circuitry allows the controller to be easily placed in a predefined default condition. On entry to this reset state, the following occur:

- The core halts program execution.
- Module registers are initialized to their defined reset values unless the bits reset only with a power-on reset.
- External port pins are forced to a known state.
- Interrupts and timers are disabled.
- Clocks to all AHB peripherals are enabled.
- Clocks to all APB peripherals other than Watchdog Timer, EMIF0, and DMAXBAR are disabled.

All registers are reset to the predefined values noted in the register descriptions unless the bits only reset with a power-on reset. The contents of RAM are unaffected during a reset; any previously stored data is preserved as long as power is not lost.

The Port I/O latches are reset to 1 in open-drain mode. Weak pullups are enabled during and after the reset. For VDD Supply Monitor and power-on resets, the $\overline{\text{RESET}}$ pin is driven low until the device exits the reset state.

On exit from the reset state, the program counter (PC) is reset, and the system clock defaults to an internal oscillator. The Watchdog Timer is enabled with the Low Frequency Oscillator (LFO0) as its clock source. Program execution begins at location 0x00000000.
