

Welcome to **E-XFL.COM** 

What is "Embedded - Microcontrollers"?

"Embedded - Microcontrollers" refer to small, integrated circuits designed to perform specific tasks within larger systems. These microcontrollers are essentially compact computers on a single chip, containing a processor core, memory, and programmable input/output peripherals. They are called "embedded" because they are embedded within electronic devices to control various functions, rather than serving as standalone computers. Microcontrollers are crucial in modern electronics, providing the intelligence and control needed for a wide range of applications.

Applications of "<u>Embedded - Microcontrollers</u>"

Details	
Product Status	Obsolete
Core Processor	ST7
Core Size	8-Bit
Speed	8MHz
Connectivity	SCI, SPI
Peripherals	LVD, POR, PWM, WDT
Number of I/O	32
Program Memory Size	8KB (8K x 8)
Program Memory Type	FLASH
EEPROM Size	-
RAM Size	384 x 8
Voltage - Supply (Vcc/Vdd)	3.8V ~ 5.5V
Data Converters	A/D 12x10b
Oscillator Type	Internal
Operating Temperature	-40°C ~ 85°C (TA)
Mounting Type	Surface Mount
Package / Case	44-LQFP
Supplier Device Package	-
Purchase URL	https://www.e-xfl.com/product-detail/stmicroelectronics/st72f324j2t6

Email: info@E-XFL.COM

Address: Room A, 16/F, Full Win Commercial Centre, 573 Nathan Road, Mongkok, Hong Kong

## **3 REGISTER & MEMORY MAP**

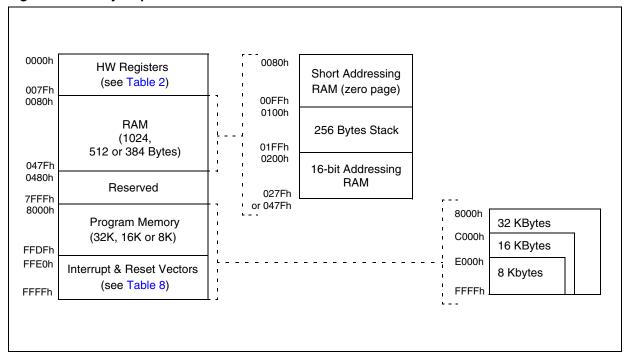

As shown in Figure 5, the MCU is capable of addressing 64K bytes of memories and I/O registers.

The available memory locations consist of 128 bytes of register locations, up to 1024 bytes of RAM and up to 32 Kbytes of user program memory. The RAM space includes up to 256 bytes for the stack from 0100h to 01FFh.

The highest address bytes contain the user reset and interrupt vectors.

**IMPORTANT:** Memory locations marked as "Reserved" must never be accessed. Accessing a reserved area can have unpredictable effects on the device.

Figure 5. Memory Map

## **CENTRAL PROCESSING UNIT (Cont'd)**

## **Condition Code Register (CC)**

Read/Write

Reset Value: 111x1xxx

The 8-bit Condition Code register contains the interrupt masks and four flags representative of the result of the instruction just executed. This register can also be handled by the PUSH and POP instructions.

These bits can be individually tested and/or controlled by specific instructions.

#### **Arithmetic Management Bits**

Bit  $4 = \mathbf{H}$  Half carry.

This bit is set by hardware when a carry occurs between bits 3 and 4 of the ALU during an ADD or ADC instructions. It is reset by hardware during the same instructions.

0: No half carry has occurred.

1: A half carry has occurred.

This bit is tested using the JRH or JRNH instruction. The H bit is useful in BCD arithmetic subroutines.

Bit 2 = N Negative.

This bit is set and cleared by hardware. It is representative of the result sign of the last arithmetic, logical or data manipulation. It's a copy of the result 7<sup>th</sup> bit.

0: The result of the last operation is positive or null.

1: The result of the last operation is negative (i.e. the most significant bit is a logic 1).

This bit is accessed by the JRMI and JRPL instructions.

Bit 1 = **Z** Zero.

This bit is set and cleared by hardware. This bit indicates that the result of the last arithmetic, logical or data manipulation is zero.

- 0: The result of the last operation is different from zero
- 1: The result of the last operation is zero.

This bit is accessed by the JREQ and JRNE test instructions.

Bit 0 = **C** Carry/borrow.

This bit is set and cleared by hardware and software. It indicates an overflow or an underflow has occurred during the last arithmetic operation.

- 0: No overflow or underflow has occurred.
- 1: An overflow or underflow has occurred.

This bit is driven by the SCF and RCF instructions and tested by the JRC and JRNC instructions. It is also affected by the "bit test and branch", shift and rotate instructions.

## **Interrupt Management Bits**

Bit 5,3 = **I1**, **I0** Interrupt

The combination of the I1 and I0 bits gives the current interrupt software priority.

Interrupt Software Priority	I1	10
Level 0 (main)	1	0
Level 1	0	1
Level 2	0	0
Level 3 (= interrupt disable)	1	1

These two bits are set/cleared by hardware when entering in interrupt. The loaded value is given by the corresponding bits in the interrupt software priority registers (IxSPR). They can be also set/cleared by software with the RIM, SIM, IRET, HALT, WFI and PUSH/POP instructions.

See the interrupt management chapter for more details.

## POWER SAVING MODES (Cont'd)

#### **8.4 ACTIVE-HALT AND HALT MODES**

ACTIVE-HALT and HALT modes are the two lowest power consumption modes of the MCU. They are both entered by executing the 'HALT' instruction. The decision to enter either in ACTIVE-HALT or HALT mode is given by the MCC/RTC interrupt enable flag (OIE bit in MCCSR register).

MCCSR OIE bit	Power Saving Mode entered when HALT instruction is executed	
0	HALT mode	
1	ACTIVE-HALT mode	

#### 8.4.1 ACTIVE-HALT MODE

ACTIVE-HALT mode is the lowest power consumption mode of the MCU with a real time clock available. It is entered by executing the 'HALT' instruction when the OIE bit of the Main Clock Controller Status register (MCCSR) is set (see Section 10.2 on page 56 for more details on the MCCSR register).

The MCU can exit ACTIVE-HALT mode on reception of either an MCC/RTC interrupt, a specific interrupt (see Table 8, "Interrupt Mapping," on page 36) or a RESET. When exiting ACTIVE-HALT mode by means of an interrupt, no 256 or 4096 CPU cycle delay occurs. The CPU resumes operation by servicing the interrupt or by fetching the reset vector which woke it up (see Figure 26). When entering ACTIVE-HALT mode, the I[1:0] bits in the CC register are forced to '10b' to enable interrupts. Therefore, if an interrupt is pending, the MCU wakes up immediately.

In ACTIVE-HALT mode, only the main oscillator and its associated counter (MCC/RTC) are running to keep a wake-up time base. All other peripherals are not clocked except those which get their clock supply from another clock generator (such as external or auxiliary oscillator).

The safeguard against staying locked in ACTIVE-HALT mode is provided by the oscillator interrupt.

**Note:** As soon as the interrupt capability of one of the oscillators is selected (MCCSR.OIE bit set), entering ACTIVE-HALT mode while the Watchdog is active does not generate a RESET.

This means that the device cannot spend more than a defined delay in this power saving mode.

**CAUTION:** When exiting ACTIVE-HALT mode following an interrupt, OIE bit of MCCSR register must not be cleared before  $t_{DELAY}$  after the interrupt occurs ( $t_{DELAY} = 256$  or 4096  $t_{CPU}$  delay de-

pending on option byte). Otherwise, the ST7 enters HALT mode for the remaining  $t_{DFLAY}$  period.

Figure 25. ACTIVE-HALT Timing Overview

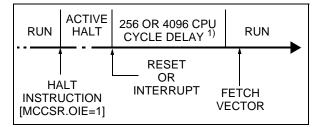

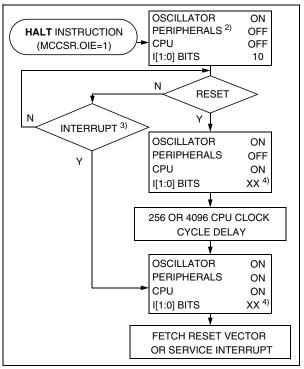

Figure 26. ACTIVE-HALT Mode Flow-chart

#### Notes:

- 1. This delay occurs only if the MCU exits ACTIVE-HALT mode by means of a RESET.
- 2. Peripheral clocked with an external clock source can still be active.
- 3. Only the MCC/RTC interrupt and some specific interrupts can exit the MCU from ACTIVE-HALT mode (such as external interrupt). Refer to Table 8, "Interrupt Mapping," on page 36 for more details.
- 4. Before servicing an interrupt, the CC register is pushed on the stack. The I[1:0] bits of the CC register are set to the current software priority level of the interrupt routine and restored when the CC register is popped.

## WATCHDOG TIMER (Cont'd)

#### 10.1.5 Low Power Modes

Mode	Description		
SLOW	No effect on	Watchdog.	
WAIT	No effect on	Watchdog.	
	OIE bit in	WDGHALT bit	
	MCCSR	in Option	
	register	Byte	
	0	0	No Watchdog reset is generated. The MCU enters Halt mode. The Watchdog counter is decremented once and then stops counting and is no longer able to generate a watchdog reset until the MCU receives an external interrupt or a reset.
HALT	HALT	0	If an external interrupt is received, the Watchdog restarts counting after 256 or 4096 CPU clocks. If a reset is generated, the Watchdog is disabled (reset state) unless Hardware Watchdog is selected by option byte. For application recommendations see Section 10.1.7 below.
	0	1	A reset is generated.
	1	x	No reset is generated. The MCU enters Active Halt mode. The Watchdog counter is not decremented. It stop counting. When the MCU receives an oscillator interrupt or external interrupt, the Watchdog restarts counting immediately. When the MCU receives a reset the Watchdog restarts counting after 256 or 4096 CPU clocks.

## 10.1.6 Hardware Watchdog Option

If Hardware Watchdog is selected by option byte, the watchdog is always active and the WDGA bit in the WDGCR is not used. Refer to the Option Byte description.

# 10.1.7 Using Halt Mode with the WDG (WDGHALT option)

The following recommendation applies if Halt mode is used when the watchdog is enabled.

 Before executing the HALT instruction, refresh the WDG counter, to avoid an unexpected WDG reset immediately after waking up the microcontroller.

## 10.1.8 Interrupts

None.

# 10.1.9 Register Description CONTROL REGISTER (WDGCR)

Read/Write

Reset Value: 0111 1111 (7Fh)

7							0
WDGA	Т6	T5	T4	ТЗ	T2	T1	ТО

#### Bit 7 = WDGA Activation bit.

This bit is set by software and only cleared by hardware after a reset. When WDGA = 1, the watchdog can generate a reset.

0: Watchdog disabled

1: Watchdog enabled

**Note:** This bit is not used if the hardware watchdog option is enabled by option byte.

Bit 6:0 = **T[6:0]** *7-bit counter (MSB to LSB).* 

These bits contain the value of the watchdog counter. It is decremented every 16384 f<sub>OSC2</sub> cycles (approx.). A reset is produced when it rolls over from 40h to 3Fh (T6 becomes cleared).

#### 10.3 16-BIT TIMER

#### 10.3.1 Introduction

The timer consists of a 16-bit free-running counter driven by a programmable prescaler.

It may be used for a variety of purposes, including pulse length measurement of up to two input signals (*input capture*) or generation of up to two output waveforms (*output compare* and *PWM*).

Pulse lengths and waveform periods can be modulated from a few microseconds to several milliseconds using the timer prescaler and the CPU clock prescaler.

Some ST7 devices have two on-chip 16-bit timers. They are completely independent, and do not share any resources. They are synchronized after a MCU reset as long as the timer clock frequencies are not modified.

This description covers one or two 16-bit timers. In ST7 devices with two timers, register names are prefixed with TA (Timer A) or TB (Timer B).

#### 10.3.2 Main Features

- Programmable prescaler: f<sub>CPU</sub> divided by 2, 4 or 8.
- Overflow status flag and maskable interrupt
- External clock input (must be at least 4 times slower than the CPU clock speed) with the choice of active edge
- 1 or 2 Output Compare functions each with:
  - 2 dedicated 16-bit registers
  - 2 dedicated programmable signals
  - 2 dedicated status flags
  - 1 dedicated maskable interrupt
- 1 or 2 Input Capture functions each with:
  - 2 dedicated 16-bit registers
  - 2 dedicated active edge selection signals
  - 2 dedicated status flags
  - 1 dedicated maskable interrupt
- Pulse width modulation mode (PWM)
- One pulse mode
- Reduced Power Mode
- 5 alternate functions on I/O ports (ICAP1, ICAP2, OCMP1, OCMP2, EXTCLK)\*

The Block Diagram is shown in Figure 35.

\*Note: Some timer pins may not be available (not bonded) in some ST7 devices. Refer to the device pin out description.

When reading an input signal on a non-bonded pin, the value will always be '1'.

## 10.3.3 Functional Description

#### 10.3.3.1 Counter

The main block of the Programmable Timer is a 16-bit free running upcounter and its associated 16-bit registers. The 16-bit registers are made up of two 8-bit registers called high & low.

Counter Register (CR):

- Counter High Register (CHR) is the most significant byte (MS Byte).
- Counter Low Register (CLR) is the least significant byte (LS Byte).

Alternate Counter Register (ACR)

- Alternate Counter High Register (ACHR) is the most significant byte (MS Byte).
- Alternate Counter Low Register (ACLR) is the least significant byte (LS Byte).

These two read-only 16-bit registers contain the same value but with the difference that reading the ACLR register does not clear the TOF bit (Timer overflow flag), located in the Status register, (SR), (see note at the end of paragraph titled 16-bit read sequence).

Writing in the CLR register or ACLR register resets the free running counter to the FFFCh value. Both counters have a reset value of FFFCh (this is the only value which is reloaded in the 16-bit timer). The reset value of both counters is also FFFCh in One Pulse mode and PWM mode.

The timer clock depends on the clock control bits of the CR2 register, as illustrated in Table 16 Clock Control Bits. The value in the counter register repeats every 131072, 262144 or 524288 CPU clock cycles depending on the CC[1:0] bits.

The timer frequency can be f<sub>CPU</sub>/2, f<sub>CPU</sub>/4, f<sub>CPU</sub>/8 or an external frequency.

**Caution:** In Flash devices, Timer A functionality has the following restrictions:

- TAOC2HR and TAOC2LR registers are write only
- Input Capture 2 is not implemented
- The corresponding interrupts cannot be used (ICF2, OCF2 forced by hardware to zero)

## 16-BIT TIMER (Cont'd)

Figure 39. Input Capture Block Diagram

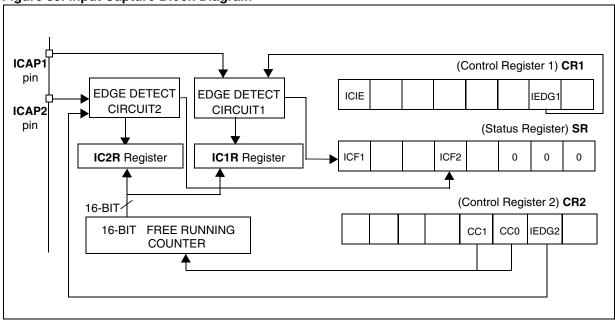

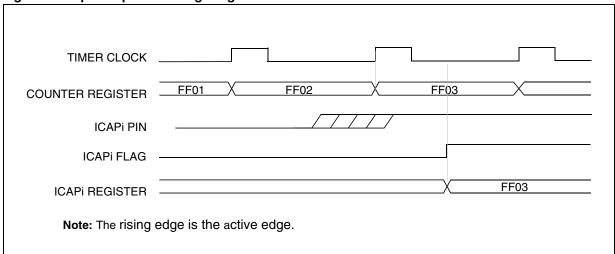

Figure 40. Input Capture Timing Diagram

47/

## 16-BIT TIMER (Cont'd)

#### 10.3.3.6 Pulse Width Modulation Mode

Pulse Width Modulation (PWM) mode enables the generation of a signal with a frequency and pulse length determined by the value of the OC1R and OC2R registers.

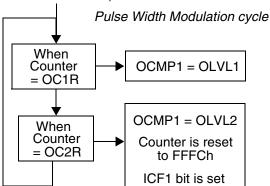

Pulse Width Modulation mode uses the complete Output Compare 1 function plus the OC2R register, and so this functionality can not be used when PWM mode is activated.

In PWM mode, double buffering is implemented on the output compare registers. Any new values written in the OC1R and OC2R registers are taken into account only at the end of the PWM period (OC2) to avoid spikes on the PWM output pin (OCMP1).

#### **Procedure**

To use pulse width modulation mode:

- Load the OC2R register with the value corresponding to the period of the signal using the formula in the opposite column.
- Load the OC1R register with the value corresponding to the period of the pulse if (OLVL1=0 and OLVL2=1) using the formula in the opposite column.
- 3. Select the following in the CR1 register:
  - Using the OLVL1 bit, select the level to be applied to the OCMP1 pin after a successful comparison with the OC1R register.
  - Using the OLVL2 bit, select the level to be applied to the OCMP1 pin after a successful comparison with the OC2R register.
- 4. Select the following in the CR2 register:
  - Set OC1E bit: the OCMP1 pin is then dedicated to the output compare 1 function.
  - Set the PWM bit.
  - Select the timer clock (CC[1:0]) (see Table 16 Clock Control Bits).

If OLVL1=1 and OLVL2=0 the length of the positive pulse is the difference between the OC2R and OC1R registers.

If OLVL1=OLVL2 a continuous signal will be seen on the OCMP1 pin.

The OCiR register value required for a specific timing application can be calculated using the following formula:

$$OCiR Value = \frac{t * f_{CPU}}{PRESC} - 5$$

Where:

t = Signal or pulse period (in seconds)

f<sub>CPU</sub> = CPU clock frequency (in hertz)

PRESC = Timer prescaler factor (2, 4 or 8 depending on CC[1:0] bits, see Table 16)

If the timer clock is an external clock the formula is:

$$OCiR = t * f_{EXT} - 5$$

Where:

= Signal or pulse period (in seconds)

f<sub>EXT</sub> = External timer clock frequency (in hertz) The Output Compare 2 event causes the counter to be initialized to FFFCh (See Figure 45)

#### Notes:

- After a write instruction to the OC/HR register, the output compare function is inhibited until the OC/LR register is also written.
- The OCF1 and OCF2 bits cannot be set by hardware in PWM mode therefore the Output Compare interrupt is inhibited.
- The ICF1 bit is set by hardware when the counter reaches the OC2R value and can produce a timer interrupt if the ICIE bit is set and the I bit is cleared
- 4. In PWM mode the ICAP1 pin can not be used to perform input capture because it is disconnected to the timer. The ICAP2 pin can be used to perform input capture (ICF2 can be set and IC2R can be loaded) but the user must take care that the counter is reset each period and ICF1 can also generates interrupt if ICIE is set.
- When the Pulse Width Modulation (PWM) and One Pulse Mode (OPM) bits are both set, the PWM mode is the only active one.
- In Flash devices, the TAOC2HR, TAOC2LR registers in Timer A are "write only". A read operation returns an undefined value.
- 7. In Flash devices, the ICAP2 registers (TAIC2HR, TAIC2LR) are not available in Timer A. The ICF2 bit is forced by hardware to 0.

## 10.5 SERIAL COMMUNICATIONS INTERFACE (SCI)

#### 10.5.1 Introduction

The Serial Communications Interface (SCI) offers a flexible means of full-duplex data exchange with external equipment requiring an industry standard NRZ asynchronous serial data format. The SCI offers a very wide range of baud rates using two baud rate generator systems.

#### 10.5.2 Main Features

- Full duplex, asynchronous communications
- NRZ standard format (Mark/Space)
- Dual baud rate generator systems
- Independently programmable transmit and receive baud rates up to 500K baud
- Programmable data word length (8 or 9 bits)
- Receive buffer full, Transmit buffer empty and End of Transmission flags
- Two receiver wake-up modes:
  - Address bit (MSB)
  - Idle line
- Muting function for multiprocessor configurations
- Separate enable bits for Transmitter and Receiver
- Four error detection flags:
  - Overrun error
  - Noise error
  - Frame error
  - Parity error
- Five interrupt sources with flags:
  - Transmit data register empty
  - Transmission complete
  - Receive data register full
  - Idle line received
  - Overrun error detected
- Parity control:
  - Transmits parity bit
  - Checks parity of received data byte
- Reduced power consumption mode

## 10.5.3 General Description

The interface is externally connected to another device by two pins (see Figure 2.):

- TDO: Transmit Data Output. When the transmitter and the receiver are disabled, the output pin returns to its I/O port configuration. When the transmitter and/or the receiver are enabled and nothing is to be transmitted, the TDO pin is at high level.
- RDI: Receive Data Input is the serial data input.
   Oversampling techniques are used for data recovery by discriminating between valid incoming data and noise.

Through these pins, serial data is transmitted and received as frames comprising:

- An Idle Line prior to transmission or reception
- A start bit
- A data word (8 or 9 bits) least significant bit first
- A Stop bit indicating that the frame is complete

  This interface uses two types of boud rate generators

This interface uses two types of baud rate generator:

- A conventional type for commonly-used baud rates
- An extended type with a prescaler offering a very wide range of baud rates even with non-standard oscillator frequencies

477

# **SERIAL COMMUNICATIONS INTERFACE** (Cont'd) **10.5.4 Functional Description**

The block diagram of the Serial Control Interface, is shown in Figure 1. It contains six dedicated registers:

- Two control registers (SCICR1 & SCICR2)
- A status register (SCISR)
- A baud rate register (SCIBRR)
- An extended prescaler receiver register (SCIER-PR)
- An extended prescaler transmitter register (SCI-ETPR)

Refer to the register descriptions in Section 0.1.7 for the definitions of each bit.

#### 10.5.4.1 Serial Data Format

Word length may be selected as being either 8 or 9 bits by programming the M bit in the SCICR1 register (see Figure 1.).

The TDO pin is in low state during the start bit.

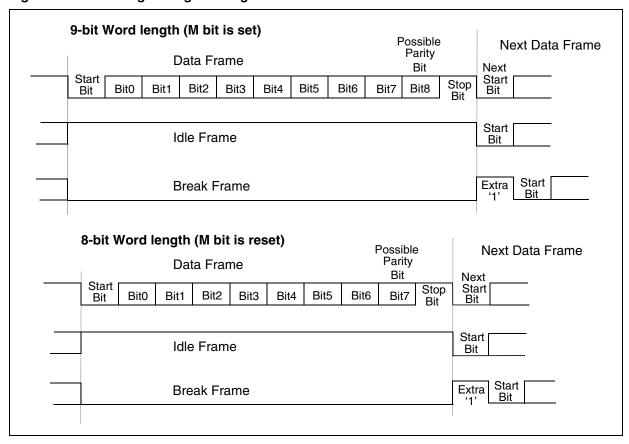

The TDO pin is in high state during the stop bit.

An Idle character is interpreted as an entire frame of "1"s followed by the start bit of the next frame which contains data.

A Break character is interpreted on receiving "0"s for some multiple of the frame period. At the end of the last break frame the transmitter inserts an extra "1" bit to acknowledge the start bit.

Transmission and reception are driven by their own baud rate generator.

Figure 54. Word Length Programming

# SERIAL COMMUNICATIONS INTERFACE (Cont'd) 10.5.4.9 Clock Deviation Causes

The causes which contribute to the total deviation are:

- D<sub>TRA</sub>: Deviation due to transmitter error (Local oscillator error of the transmitter or the transmitter is transmitting at a different baud rate).
- D<sub>QUANT</sub>: Error due to the baud rate quantization of the receiver.
- D<sub>REC</sub>: Deviation of the local oscillator of the receiver: This deviation can occur during the reception of one complete SCI message assuming that the deviation has been compensated at the beginning of the message.
- D<sub>TCL</sub>: Deviation due to the transmission line (generally due to the transceivers)

All the deviations of the system should be added and compared to the SCI clock tolerance:

 $D_{TRA} + D_{QUANT} + D_{REC} + D_{TCL} < 3.75\%$ 

#### 10.5.4.10 Noise Error Causes

See also description of Noise error in Section 0.1.4.3.

#### Start bit

The noise flag (NF) is set during start bit reception if one of the following conditions occurs:

- A valid falling edge is not detected. A falling edge is considered to be valid if the 3 consecutive samples before the falling edge occurs are detected as '1' and, after the falling edge occurs, during the sampling of the 16 samples, if one of the samples numbered 3, 5 or 7 is detected as a "1".
- During sampling of the 16 samples, if one of the samples numbered 8, 9 or 10 is detected as a "1".

Therefore, a valid Start Bit must satisfy both the above conditions to prevent the Noise Flag getting set.

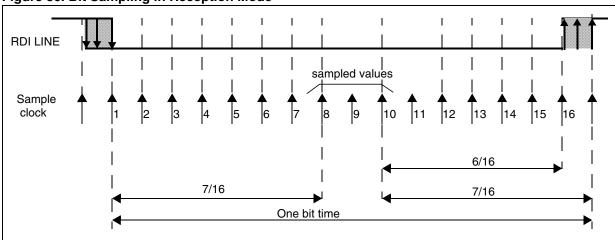

#### **Data Bits**

The noise flag (NF) is set during normal data bit reception if the following condition occurs:

 During the sampling of 16 samples, if all three samples numbered 8, 9 and 10 are not the same.
 The majority of the 8th, 9th and 10th samples is considered as the bit value.

Therefore, a valid Data Bit must have samples 8, 9 and 10 at the same value to prevent the Noise Flag getting set.

## 10.6 10-BIT A/D CONVERTER (ADC)

#### 10.6.1 Introduction

The on-chip Analog to Digital Converter (ADC) peripheral is a 10-bit, successive approximation converter with internal sample and hold circuitry. This peripheral has up to 16 multiplexed analog input channels (refer to device pin out description) that allow the peripheral to convert the analog voltage levels from up to 16 different sources.

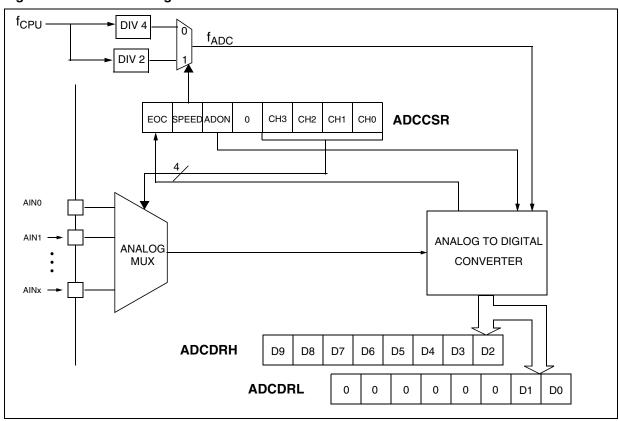

The result of the conversion is stored in a 10-bit Data Register. The A/D converter is controlled through a Control/Status Register.

#### 10.6.2 Main Features

- 10-bit conversion
- Up to 16 channels with multiplexed input
- Linear successive approximation
- Data register (DR) which contains the results
- Conversion complete status flag
- On/off bit (to reduce consumption)

The block diagram is shown in Figure 57.

Figure 57. ADC Block Diagram

## **CLOCK AND TIMING CHARACTERISTICS** (Cont'd)

## 12.6.3 Crystal and Ceramic Resonator Oscillators

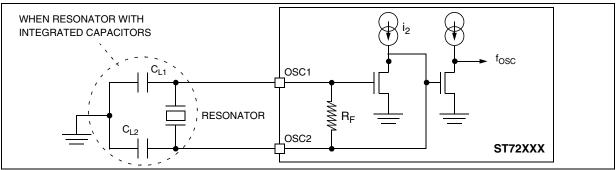

The ST7 internal clock can be supplied with four different Crystal/Ceramic resonator oscillators. All the information given in this paragraph are based on characterization results with specified typical external components. In the application, the resonator and the load capacitors have to be placed as

close as possible to the oscillator pins in order to minimize output distortion and start-up stabilization time. Refer to the crystal/ceramic resonator manufacturer for more details (frequency, package, accuracy...).

Symbol	Parameter	Con	Conditions		Max	Unit
		LP: Low power	oscillator	1	2	
£	Oscillator Fraguency 1)	MP: Medium po	ower oscillator	>2	4	MHz

			HS oscillator	610	910	

Figure 66. Typical Application with a Crystal or Ceramic Resonator

#### Notes:

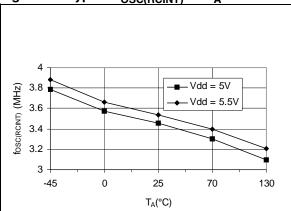

- 1. The oscillator selection can be optimized in terms of supply current using an high quality resonator with small  $R_S$  value. Refer to crystal/ceramic resonator manufacturer for more details.
- 2. Data based on characterisation results, not tested in production.

# **CLOCK CHARACTERISTICS** (Cont'd)

## 12.6.4 RC Oscillators

Symbol	Parameter	Conditions	Min	Тур	Max	Unit
f	Internal RC oscillator frequency	T <sub>A</sub> =25°C, V <sub>DD</sub> =5V	2	3.5	5.6	MHz
IOSC (RCINT)	See Figure 67	1 <sub>A</sub> -23 C, V <sub>DD</sub> -3V	2	3.5	5.0	IVIITZ

**Note:** To reduce disturbance to the RC oscillator, it is recommended to place decoupling capacitors between  $V_{DD}$  and  $V_{SS}$  as shown in Figure 86

#### 12.9 I/O PORT PIN CHARACTERISTICS

#### 12.9.1 General Characteristics

Subject to general operating conditions for V<sub>DD</sub>, f<sub>OSC</sub>, and T<sub>A</sub> unless otherwise specified.

Symbol	Parameter	Conditions	Min	Тур	Max	Unit
V <sub>IL</sub>	Input low level voltage (standard voltage devices) <sup>1)</sup>				0.3xV <sub>DD</sub>	V
V <sub>IH</sub>	Input high level voltage 1)		$0.7xV_{DD}$			V
V <sub>hys</sub>	Schmitt trigger voltage hysteresis <sup>2)</sup>			0.7		V
3)	Injected Current on Flash device pin PB0		0		+4

t <sub>r(IO)out</sub>	Output low to high level rise time 1)	Between 10% and 90%		25		ns
t <sub>w(IT)in</sub>	External interrupt pulse time <sup>6)</sup>		1			t <sub>CPU</sub>

#### Notes:

- 1. Data based on characterization results, not tested in production.
- 2. Hysteresis voltage between Schmitt trigger switching levels. Based on characterization results, not tested.
- 3. When the current limitation is not possible, the  $V_{IN}$  maximum must be respected, otherwise refer to  $I_{INJ(PIN)}$  specification. A positive injection is induced by  $V_{IN} > V_{DD}$  while a negative injection is induced by  $V_{IN} < V_{SS}$ . Refer to Section 12.2.2 on page 117 for more details.
- 4. Configuration not recommended, all unused pins must be kept at a fixed voltage: using the output mode of the I/O for example and leaving the I/O unconnected on the board or an external pull-up or pull-down resistor (see Figure 69). Data based on design simulation and/or technology characteristics, not tested in production.
- 5. The RPU pull-up equivalent resistor is based on a resistive transistor (corresponding IPU current characteristics described in Figure 70).
- 6. To generate an external interrupt, a minimum pulse width has to be applied on an I/O port pin configured as an external interrupt source.

Figure 69. Unused I/O Pins configured as input

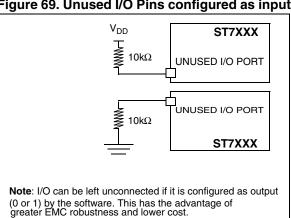

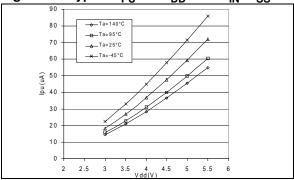

Figure 70. Typical  $I_{PIJ}$  vs.  $V_{DD}$  with  $V_{IN}=V_{SS}$ 

#### 12.12 COMMUNICATION INTERFACE CHARACTERISTICS

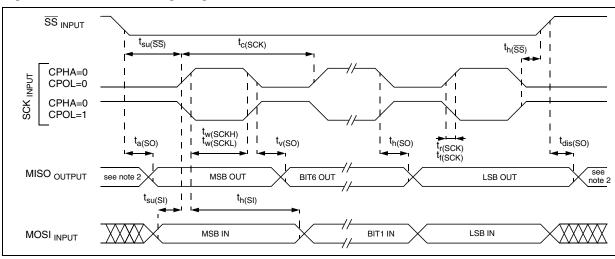

## 12.12.1 SPI - Serial Peripheral Interface

Subject to general operating conditions for  $V_{DD}$ ,  $f_{CPU}$ , and  $T_A$  unless otherwise specified. Data based on design simulation and/or characterisation results, not tested in production.

When no communication is on-going the data output line of the SPI (MOSI in master mode, MISO in slave mode) has its alternate function capability released. In this case, the pin status depends on the I/O port configuration. Refer to I/O port characteristics for more details on the input/output alternate function characteristics (SS, SCK, MOSI, MISO).

Symbol	Parameter	Conditions	Min	Max	Unit
f <sub>SCK</sub>	SPI clock frequency	Master f <sub>CPU</sub> =8MHz	f <sub>CPU</sub> /128 0.0625	f <sub>CPU</sub> /4 2	MHz

Figure 80. SPI Slave Timing Diagram with CPHA=0 1)

#### Notes:

140/164

1. Measurement points are done at CMOS levels: 0.3xV<sub>DD</sub> and 0.7xV<sub>DD</sub>.

## 10-BIT ADC CHARACTERISTICS (Cont'd)

## 12.13.3 ADC Accuracy

Conditions: V<sub>DD</sub>=5V 1)

Cumbal	Parameter	Conditions	Flash I	Unit	
Symbol	Parameter	Conditions		Max <sup>2)</sup>	Offic
IE <sub>T</sub> I	Total unadjusted error 1)		4	6	
IE <sub>O</sub> I	Offset error 1)		3	5	
IE <sub>G</sub> I	Gain Error 1)		0.5	4.5	LSB
IE <sub>D</sub> I	Differential linearity error 1)	CPU in run mode @ f <sub>ADC</sub> 2 MHz.	1.5	4.5	202
IE <sub>L</sub> I	Integral linearity error 1)	CPU in run mode @ f <sub>ADC</sub> 2 MHz.	1.5	4.5	

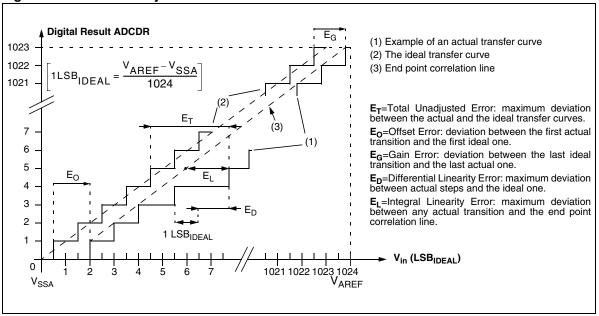

#### Notes:

1. ADC Accuracy vs. Negative Injection Current: Injecting negative current may reduce the accuracy of the conversion being performed on another analog input.

Any positive injection current within the limits specified for  $I_{INJ(PIN)}$  and  $\Sigma I_{INJ(PIN)}$  in Section 12.9 does not affect the ADC accuracy.

2. Data based on characterization results, monitored in production to guarantee 99.73% within  $\pm$  max value from -40°C to 125°C ( $\pm$  3 $\sigma$  distribution limits).

#### 15.1.7 16-bit Timer PWM Mode

In PWM mode, the first PWM pulse is missed after writing the value FFFCh in the OC1R register (OC1HR, OC1LR). It leads to either full or no PWM during a period, depending on the OLVL1 and OLVL2 settings.

#### 15.1.8 SCI Wrong Break duration

#### Description

A single break character is sent by setting and resetting the SBK bit in the SCICR2 register. In some cases, the break character may have a longer duration than expected:

- 20 bits instead of 10 bits if M=0
- 22 bits instead of 11 bits if M=1.

In the same way, as long as the SBK bit is set, break characters are sent to the TDO pin. This may lead to generate one break more than expected

#### Occurrence

The occurrence of the problem is random and proportional to the baudrate. With a transmit frequency of 19200 baud (fCPU=8MHz and SCI-BRR=0xC9), the wrong break duration occurrence is around 1%.

#### Workaround

If this wrong duration is not compliant with the communication protocol in the application, software can request that an Idle line be generated before the break character. In this case, the break duration is always correct assuming the application is not doing anything between the idle and the break. This can be ensured by temporarily disabling interrupts.

The exact sequence is:

- Disable interrupts
- Reset and Set TE (IDLE request)
- Set and Reset SBK (Break Request)
- Re-enable interrupts

#### 15.2 FLASH DEVICES ONLY

#### 15.2.1 Internal RC Operation

In ST72F324J and ST72F324K devices, the internal RC oscillator is not supported if the LVD is disabled.
