

Welcome to **E-XFL.COM** 

What is "Embedded - Microcontrollers"?

"Embedded - Microcontrollers" refer to small, integrated circuits designed to perform specific tasks within larger systems. These microcontrollers are essentially compact computers on a single chip, containing a processor core, memory, and programmable input/output peripherals. They are called "embedded" because they are embedded within electronic devices to control various functions, rather than serving as standalone computers. Microcontrollers are crucial in modern electronics, providing the intelligence and control needed for a wide range of applications.

Applications of "<u>Embedded - Microcontrollers</u>"

Details	
Product Status	Obsolete
Core Processor	ST7
Core Size	8-Bit
Speed	8MHz
Connectivity	SCI, SPI
Peripherals	LVD, POR, PWM, WDT
Number of I/O	24
Program Memory Size	16KB (16K x 8)
Program Memory Type	FLASH
EEPROM Size	-
RAM Size	512 x 8
Voltage - Supply (Vcc/Vdd)	3.8V ~ 5.5V
Data Converters	A/D 8x10b
Oscillator Type	Internal
Operating Temperature	-40°C ~ 85°C (TA)
Mounting Type	Surface Mount
Package / Case	32-LQFP
Supplier Device Package	-
Purchase URL	https://www.e-xfl.com/product-detail/stmicroelectronics/st72f324k4t6

Email: info@E-XFL.COM

Address: Room A, 16/F, Full Win Commercial Centre, 573 Nathan Road, Mongkok, Hong Kong

## **5 CENTRAL PROCESSING UNIT**

#### 5.1 INTRODUCTION

This CPU has a full 8-bit architecture and contains six internal registers allowing efficient 8-bit data manipulation.

#### **5.2 MAIN FEATURES**

- Enable executing 63 basic instructions
- Fast 8-bit by 8-bit multiply
- 17 main addressing modes (with indirect addressing mode)
- Two 8-bit index registers
- 16-bit stack pointer
- Low power HALT and WAIT modes
- Priority maskable hardware interrupts
- Non-maskable software/hardware interrupts

### **5.3 CPU REGISTERS**

The 6 CPU registers shown in Figure 8 are not present in the memory mapping and are accessed by specific instructions.

## Accumulator (A)

The Accumulator is an 8-bit general purpose register used to hold operands and the results of the arithmetic and logic calculations and to manipulate data.

## Index Registers (X and Y)

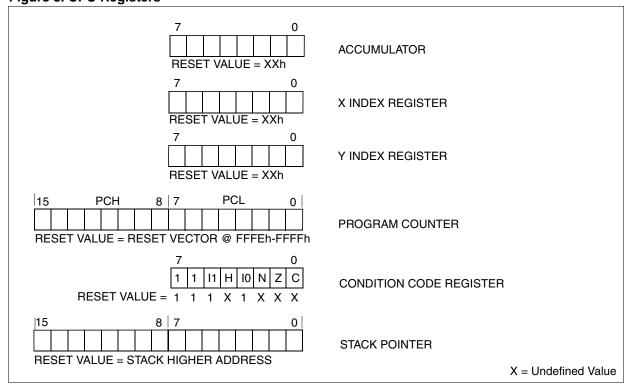

These 8-bit registers are used to create effective addresses or as temporary storage areas for data manipulation. (The Cross-Assembler generates a precede instruction (PRE) to indicate that the following instruction refers to the Y register.)

The Y register is not affected by the interrupt automatic procedures.

## **Program Counter (PC)**

The program counter is a 16-bit register containing the address of the next instruction to be executed by the CPU. It is made of two 8-bit registers PCL (Program Counter Low which is the LSB) and PCH (Program Counter High which is the MSB).

Figure 8. CPU Registers

## WATCHDOG TIMER (Cont'd)

#### 10.1.5 Low Power Modes

Mode	Description		
SLOW	No effect on	Watchdog.	
WAIT	No effect on	Watchdog.	
	OIE bit in	WDGHALT bit	
	MCCSR	in Option	
	register	Byte	
	0	0	No Watchdog reset is generated. The MCU enters Halt mode. The Watchdog counter is decremented once and then stops counting and is no longer able to generate a watchdog reset until the MCU receives an external interrupt or a reset.
HALT	U	0	If an external interrupt is received, the Watchdog restarts counting after 256 or 4096 CPU clocks. If a reset is generated, the Watchdog is disabled (reset state) unless Hardware Watchdog is selected by option byte. For application recommendations see Section 10.1.7 below.
	0	1	A reset is generated.
	1	x	No reset is generated. The MCU enters Active Halt mode. The Watchdog counter is not decremented. It stop counting. When the MCU receives an oscillator interrupt or external interrupt, the Watchdog restarts counting immediately. When the MCU receives a reset the Watchdog restarts counting after 256 or 4096 CPU clocks.

## 10.1.6 Hardware Watchdog Option

If Hardware Watchdog is selected by option byte, the watchdog is always active and the WDGA bit in the WDGCR is not used. Refer to the Option Byte description.

# 10.1.7 Using Halt Mode with the WDG (WDGHALT option)

The following recommendation applies if Halt mode is used when the watchdog is enabled.

 Before executing the HALT instruction, refresh the WDG counter, to avoid an unexpected WDG reset immediately after waking up the microcontroller.

# 10.1.8 Interrupts

None.

# 10.1.9 Register Description CONTROL REGISTER (WDGCR)

Read/Write

Reset Value: 0111 1111 (7Fh)

7							0
WDGA	Т6	T5	T4	ТЗ	T2	T1	ТО

## Bit 7 = WDGA Activation bit.

This bit is set by software and only cleared by hardware after a reset. When WDGA = 1, the watchdog can generate a reset.

0: Watchdog disabled

1: Watchdog enabled

**Note:** This bit is not used if the hardware watchdog option is enabled by option byte.

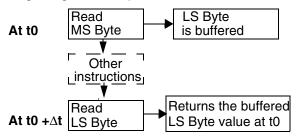

Bit 6:0 = **T[6:0]** *7-bit counter (MSB to LSB).* 

These bits contain the value of the watchdog counter. It is decremented every 16384 f<sub>OSC2</sub> cycles (approx.). A reset is produced when it rolls over from 40h to 3Fh (T6 becomes cleared).

## 16-BIT TIMER (Cont'd)

**16-bit read sequence:** (from either the Counter Register or the Alternate Counter Register).

Beginning of the sequence

Sequence completed

The user must read the MS Byte first, then the LS Byte value is buffered automatically.

This buffered value remains unchanged until the 16-bit read sequence is completed, even if the user reads the MS Byte several times.

After a complete reading sequence, if only the CLR register or ACLR register are read, they return the LS Byte of the count value at the time of the read.

Whatever the timer mode used (input capture, output compare, one pulse mode or PWM mode) an overflow occurs when the counter rolls over from FFFFh to 0000h then:

- The TOF bit of the SR register is set.
- A timer interrupt is generated if:
  - TOIE bit of the CR1 register is set and
  - I bit of the CC register is cleared.

If one of these conditions is false, the interrupt remains pending to be issued as soon as they are both true.

Clearing the overflow interrupt request is done in two steps:

- 1. Reading the SR register while the TOF bit is set.
- 2. An access (read or write) to the CLR register.

**Notes:** The TOF bit is not cleared by accesses to ACLR register. The advantage of accessing the ACLR register rather than the CLR register is that it allows simultaneous use of the overflow function and reading the free running counter at random times (for example, to measure elapsed time) without the risk of clearing the TOF bit erroneously.

The timer is not affected by WAIT mode.

In HALT mode, the counter stops counting until the mode is exited. Counting then resumes from the previous count (MCU awakened by an interrupt) or from the reset count (MCU awakened by a Reset).

## 10.3.3.2 External Clock

The external clock (where available) is selected if CC0=1 and CC1=1 in the CR2 register.

The status of the EXEDG bit in the CR2 register determines the type of level transition on the external clock pin EXTCLK that will trigger the free running counter.

The counter is synchronized with the falling edge of the internal CPU clock.

A minimum of four falling edges of the CPU clock must occur between two consecutive active edges of the external clock; thus the external clock frequency must be less than a quarter of the CPU clock frequency.

# 16-BIT TIMER (Cont'd)

Figure 39. Input Capture Block Diagram

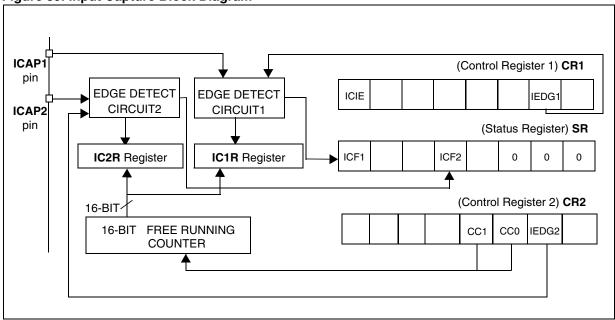

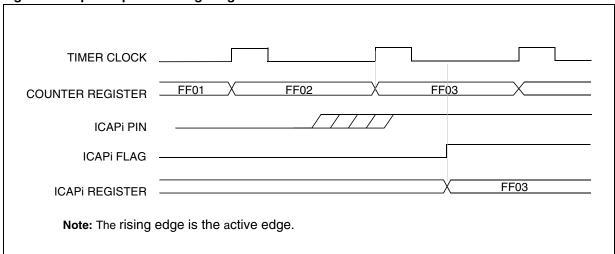

Figure 40. Input Capture Timing Diagram

47/

## 16-BIT TIMER (Cont'd)

## **CONTROL REGISTER 2 (CR2)**

Read/Write

Reset Value: 0000 0000 (00h)

7 0
OC1E OC2E OPM PWM CC1 CC0 IEDG2 EXEDG

## Bit 7 = **OC1E** Output Compare 1 Pin Enable.

This bit is used only to output the signal from the timer on the OCMP1 pin (OLV1 in Output Compare mode, both OLV1 and OLV2 in PWM and one-pulse mode). Whatever the value of the OC1E bit, the Output Compare 1 function of the timer remains active.

- 0: OCMP1 pin alternate function disabled (I/O pin free for general-purpose I/O).
- 1: OCMP1 pin alternate function enabled.

## Bit 6 = **OC2E** Output Compare 2 Pin Enable.

This bit is used only to output the signal from the timer on the OCMP2 pin (OLV2 in Output Compare mode). Whatever the value of the OC2E bit, the Output Compare 2 function of the timer remains active.

- 0: OCMP2 pin alternate function disabled (I/O pin free for general-purpose I/O).
- 1: OCMP2 pin alternate function enabled.

**Note:** In Flash devices, this bit is not available for Timer A. It must be kept at its reset value.

## Bit 5 = **OPM** One Pulse Mode.

- 0: One Pulse Mode is not active.
- 1: One Pulse Mode is active, the ICAP1 pin can be used to trigger one pulse on the OCMP1 pin; the active transition is given by the IEDG1 bit. The length of the generated pulse depends on the contents of the OC1R register.

Bit 4 = **PWM** Pulse Width Modulation.

- 0: PWM mode is not active.
- 1: PWM mode is active, the OCMP1 pin outputs a programmable cyclic signal; the length of the pulse depends on the value of OC1R register; the period depends on the value of OC2R register.

# Bit 3, 2 = CC[1:0] Clock Control.

The timer clock mode depends on these bits:

Table 16. Clock Control Bits

Timer Clock	CC1	CC0
f <sub>CPU</sub> / 4	0	0
f <sub>CPU</sub> / 2	0	1
f <sub>CPU</sub> / 8	1	0
External Clock (where available)	1	1

**Note**: If the external clock pin is not available, programming the external clock configuration stops the counter.

## Bit 1 = **IEDG2** Input Edge 2.

This bit determines which type of level transition on the ICAP2 pin will trigger the capture.

- 0: A falling edge triggers the capture.
- 1: A rising edge triggers the capture.

## Bit 0 = **EXEDG** External Clock Edge.

This bit determines which type of level transition on the external clock pin EXTCLK will trigger the counter register.

- 0: A falling edge triggers the counter register.
- 1: A rising edge triggers the counter register.

## SERIAL PERIPHERAL INTERFACE (Cont'd)

## 10.4.3.3 Master Mode Operation

In master mode, the serial clock is output on the SCK pin. The clock frequency, polarity and phase are configured by software (refer to the description of the SPICSR register).

**Note:** The idle state of SCK must correspond to the polarity selected in the SPICSR register (by pulling up SCK if CPOL=1 or pulling down SCK if CPOL=0).

To operate the SPI in master mode, perform the following steps in order (if the SPICSR register is not written first, the SPICR register setting (MSTR bit) may be not taken into account):

- 1. Write to the SPICR register:
  - Select the clock frequency by configuring the SPR[2:0] bits.
  - Select the clock polarity and clock phase by configuring the CPOL and CPHA bits. Figure 50 shows the four possible configurations.
     Note: The slave must have the same CPOL and CPHA settings as the master.
- 2. Write to the SPICSR register:
  - Either set the SSM bit and set the SSI bit or clear the SSM bit and tie the SS pin high for the complete byte transmit sequence.
- 3. Write to the SPICR register:
  - Set the MSTR and SPE bits
     Note: MSTR and SPE bits remain set only if SS is high).

The transmit sequence begins when software writes a byte in the SPIDR register.

## 10.4.3.4 Master Mode Transmit Sequence

When software writes to the SPIDR register, the data byte is loaded into the 8-bit shift register and then shifted out serially to the MOSI pin most significant bit first.

When data transfer is complete:

- The SPIF bit is set by hardware
- An interrupt request is generated if the SPIE bit is set and the interrupt mask in the CCR register is cleared.

Clearing the SPIF bit is performed by the following software sequence:

- An access to the SPICSR register while the SPIF bit is set
- A read to the SPIDR register.

**Note:** While the SPIF bit is set, all writes to the SPIDR register are inhibited until the SPICSR register is read.

## 10.4.3.5 Slave Mode Operation

In slave mode, the serial clock is received on the SCK pin from the master device.

To operate the SPI in slave mode:

- Write to the SPICSR register to perform the following actions:
  - Select the clock polarity and clock phase by configuring the CPOL and CPHA bits (see Figure 50).

Figure 50).

Note: The slave must have the same CPOL and CPHA settings as the master.

- Manage the SS pin as described in Section 10.4.3.2 and Figure 48. If CPHA=1 SS must be held low continuously. If CPHA=0 SS must be held low during byte transmission and pulled up between each byte to let the slave write in the shift register.
- Write to the SPICR register to clear the MSTR bit and set the SPE bit to enable the SPI I/O functions.

## 10.4.3.6 Slave Mode Transmit Sequence

When software writes to the SPIDR register, the data byte is loaded into the 8-bit shift register and then shifted out serially to the MISO pin most significant bit first.

The transmit sequence begins when the slave device receives the clock signal and the most significant bit of the data on its MOSI pin.

When data transfer is complete:

- The SPIF bit is set by hardware
- An interrupt request is generated if SPIE bit is set and interrupt mask in the CCR register is cleared.

Clearing the SPIF bit is performed by the following software sequence:

- An access to the SPICSR register while the SPIF bit is set.
- 2. A write or a read to the SPIDR register.

**Notes:** While the SPIF bit is set, all writes to the SPIDR register are inhibited until the SPICSR register is read.

The SPIF bit can be cleared during a second transmission; however, it must be cleared before the second SPIF bit in order to prevent an Overrun condition (see Section 10.4.5.2).

## SERIAL PERIPHERAL INTERFACE (Cont'd)

## 10.4.5 Error Flags

## 10.4.5.1 Master Mode Fault (MODF)

Master  $\underline{\mathsf{mode}}$  fault occurs when the master device has its  $\overline{\mathsf{SS}}$  pin pulled low.

When a Master mode fault occurs:

- The MODF bit is set and an SPI interrupt request is generated if the SPIE bit is set.
- The SPE bit is reset. This blocks all output from the device and disables the SPI peripheral.
- The MSTR bit is reset, thus forcing the device into slave mode.

Clearing the MODF bit is done through a software sequence:

- A read access to the SPICSR register while the MODF bit is set.
- 2. A write to the SPICR register.

**Notes:** To avoid any conflicts in an application with multiple slaves, the  $\overline{SS}$  pin must be pulled high during the MODF bit clearing sequence. The SPE and MSTR bits may be restored to their original state during or after this clearing sequence.

Hardware does not allow the user to set the SPE and MSTR bits while the MODF bit is set except in the MODF bit clearing sequence.

## 10.4.5.2 Overrun Condition (OVR)

An overrun condition occurs, when the master device has sent a data byte and the slave device has

not cleared the SPIF bit issued from the previously transmitted byte.

When an Overrun occurs:

 The OVR bit is set and an interrupt request is generated if the SPIE bit is set.

In this case, the receiver buffer contains the byte sent after the SPIF bit was last cleared. A read to the SPIDR register returns this byte. All other bytes are lost.

The OVR bit is cleared by reading the SPICSR register.

## 10.4.5.3 Write Collision Error (WCOL)

A write collision occurs when the software tries to write to the SPIDR register while a data transfer is taking place with an external device. When this happens, the transfer continues uninterrupted; and the software write will be unsuccessful.

Write collisions can occur both in master and slave mode. See also Section 10.4.3.2 Slave Select Management.

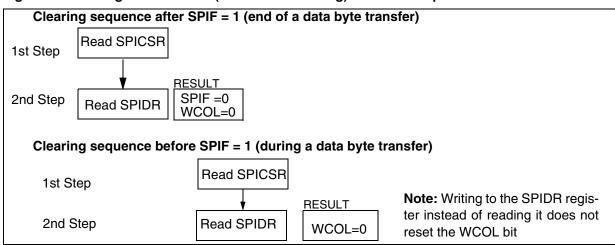

**Note:** a "read collision" will never occur since the received data byte is placed in a buffer in which access is always synchronous with the MCU operation.

The WCOL bit in the SPICSR register is set if a write collision occurs.

No SPI interrupt is generated when the WCOL bit is set (the WCOL bit is a status flag only).

Clearing the WCOL bit is done through a software sequence (see Figure 51).

Figure 51. Clearing the WCOL bit (Write Collision Flag) Software Sequence

# SERIAL COMMUNICATIONS INTERFACE (Cont'd)

## 10.5.4.3 Receiver

The SCI can receive data words of either 8 or 9 bits. When the M bit is set, word length is 9 bits and the MSB is stored in the R8 bit in the SCICR1 register.

## Character reception

During a SCI reception, data shifts in least significant bit first through the RDI pin. In this mode, the SCIDR register consists or a buffer (RDR) between the internal bus and the received shift register (see Figure 1.).

### **Procedure**

- Select the M bit to define the word length.
- Select the desired baud rate using the SCIBRR and the SCIERPR registers.
- Set the RE bit, this enables the receiver which begins searching for a start bit.

When a character is received:

- The RDRF bit is set. It indicates that the content of the shift register is transferred to the RDR.
- An interrupt is generated if the RIE bit is set and the I bit is cleared in the CCR register.
- The error flags can be set if a frame error, noise or an overrun error has been detected during reception.

Clearing the RDRF bit is performed by the following software sequence done by:

- An access to the SCISR register
- 2. A read to the SCIDR register.

The RDRF bit must be cleared before the end of the reception of the next character to avoid an overrun error.

#### **Break Character**

When a break character is received, the SCI handles it as a framing error.

## **Idle Character**

When a idle frame is detected, there is the same procedure as a data received character plus an interrupt if the ILIE bit is set and the I bit is cleared in the CCR register.

## **Overrun Error**

An overrun error occurs when a character is received when RDRF has not been reset. Data can not be transferred from the shift register to the

RDR register as long as the RDRF bit is not cleared.

When an overrun error occurs:

- The OR bit is set.
- The RDR content is not lost.
- The shift register is overwritten.
- An interrupt is generated if the RIE bit is set and the I bit is cleared in the CCR register.

The OR bit is reset by an access to the SCISR register followed by a SCIDR register read operation.

#### Noise Error

Oversampling techniques are used for data recovery by discriminating between valid incoming data and noise. Normal data bits are considered valid if three consecutive samples (8th, 9th, 10th) have the same bit value, otherwise the NF flag is set. In the case of start bit detection, the NF flag is set on the basis of an algorithm combining both valid edge detection and three samples (8th, 9th, 10th). Therefore, to prevent the NF flag getting set during start bit reception, there should be a valid edge detection as well as three valid samples.

When noise is detected in a frame:

- The NF flag is set at the rising edge of the RDRF hit
- Data is transferred from the Shift register to the SCIDR register.
- No interrupt is generated. However this bit rises at the same time as the RDRF bit which itself generates an interrupt.

The NF flag is reset by a SCISR register read operation followed by a SCIDR register read operation.

During reception, if a false start bit is detected (e.g. 8th, 9th, 10th samples are 011,101,110), the frame is discarded and the receiving sequence is not started for this frame. There is no RDRF bit set for this frame and the NF flag is set internally (not accessible to the user). This NF flag is accessible along with the RDRF bit when a next valid frame is received.

**Note:** If the application Start Bit is not long enough to match the above requirements, then the NF Flag may get set due to the short Start Bit. In this case, the NF flag may be ignored by the application software when the first valid byte is received.

See also Section 0.1.4.10.

# INSTRUCTION SET OVERVIEW (Cont'd)

Mnemo	Description	Function/Example	Dst	Src	l1	Н	10	N	Z	С

Symbol	Parameter	Conditions	Min	Max	Unit
$V_{IL}$	Input low level voltage 1)		$V_{SS}$	0.2	V
V <sub>IH</sub>	Input high level voltage 1)		V <sub>DD</sub> -0.1	12.6	V
IL	Input leakage current	V <sub>IN</sub> =V <sub>SS</sub>		±1	μΑ

Figure 79. Two typical Applications with ICCSEL/V<sub>PP</sub> Pin <sup>2)</sup>

## Notes:

- 1. Data based on design simulation and/or technology characteristics, not tested in production.
- 2. When ICC mode is not required by the application ICCSEL/V<sub>PP</sub> pin must be tied to V<sub>SS</sub>.

## ADC CHARACTERISTICS (Cont'd)

Figure 83. R<sub>AIN</sub> max. vs f<sub>ADC</sub> with C<sub>AIN</sub>=0pF<sup>1)</sup>

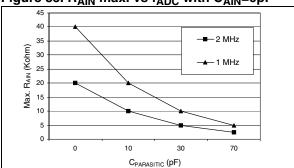

Figure 84. Recommended C<sub>AIN</sub> & R<sub>AIN values.</sub><sup>2)</sup>

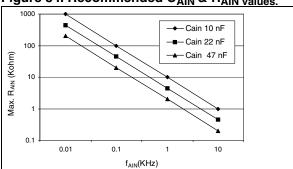

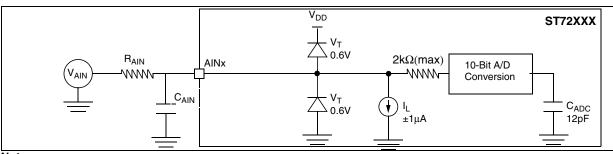

Figure 85. Typical A/D Converter Application

#### Notes:

- 1. C<sub>PARASITIC</sub> represents the capacitance of the PCB (dependent on soldering and PCB layout quality) plus the pad capacitance (3pF). A high C<sub>PARASITIC</sub> value will downgrade conversion accuracy. To remedy this, f<sub>ADC</sub> should be reduced.

  2. This graph shows that depending on the input signal variation (f<sub>AIN</sub>), C<sub>AIN</sub> can be increased for stabilization time and
- 2. This graph shows that depending on the input signal variation ( $f_{AIN}$ ),  $C_{AIN}$  can be increased for stabilization time and decreased to allow the use of a larger serial resistor ( $R_{AIN}$ ).

## 10-BIT ADC CHARACTERISTICS (Cont'd)

## 12.13.3 ADC Accuracy

Conditions: V<sub>DD</sub>=5V 1)

Cumbal	Parameter	Conditions -		Flash Devices		
Symbol	Parameter			Max <sup>2)</sup>	Unit	
IE <sub>T</sub> I	Total unadjusted error 1)		4	6		
IE <sub>O</sub> I	Offset error 1)		3	5		
IE <sub>G</sub> I	Gain Error 1)		0.5	4.5	LSB	
IE <sub>D</sub> I	Differential linearity error 1)	CPU in run mode @ f <sub>ADC</sub> 2 MHz.	1.5	4.5	202	
IE <sub>L</sub> I	Integral linearity error 1)	CPU in run mode @ f <sub>ADC</sub> 2 MHz.	1.5	4.5		

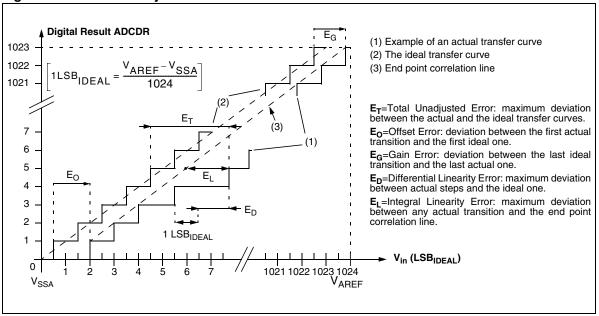

#### Notes:

1. ADC Accuracy vs. Negative Injection Current: Injecting negative current may reduce the accuracy of the conversion being performed on another analog input.

Any positive injection current within the limits specified for  $I_{INJ(PIN)}$  and  $\Sigma I_{INJ(PIN)}$  in Section 12.9 does not affect the ADC accuracy.

2. Data based on characterization results, monitored in production to guarantee 99.73% within  $\pm$  max value from -40°C to 125°C ( $\pm$  3 $\sigma$  distribution limits).

## 15 KNOWN LIMITATIONS

## 15.1 ALL DEVICES

## 15.1.1 External RC option

The External RC clock source option described in previous datasheet revisions is no longer supported and has been removed from this specification.

#### 15.1.2 CSS Function

The Clock Security System function has been removed from the datasheet.

#### 15.1.3 Safe Connection of OSC1/OSC2 Pins

The OSC1 and/or OSC2 pins must not be left unconnected otherwise the ST7 main oscillator may start and, in this configuration, could generate an f<sub>OSC</sub> clock frequency in excess of the allowed maximum (>16MHz.), putting the ST7 in an unsafe/undefined state. Refer to Section 6.2 on page 24.

## 15.1.4 Unexpected Reset Fetch

If an interrupt request occurs while a "POP CC" instruction is executed, the interrupt controller does not recognise the source of the interrupt and, by default, passes the RESET vector address to the CPU.

#### Workaround

To solve this issue, a "POP CC" instruction must always be preceded by a "SIM" instruction.

# 15.1.5 Clearing active interrupts outside interrupt routine

When an active interrupt request occurs at the same time as the related flag is being cleared, an unwanted reset may occur.

**Note:** clearing the related interrupt mask will not generate an unwanted reset

### Concurrent interrupt context

The symptom does not occur when the interrupts are handled normally, i.e.

#### when:

- The interrupt flag is cleared within its own interrupt routine
- The interrupt flag is cleared within any interrupt routine
- The interrupt flag is cleared in any part of the code while this interrupt is disabled

If these conditions are not met, the symptom can be avoided by implementing the following sequence:

Perform SIM and RIM operation before and after resetting an active interrupt request.

## Example:

SIM

reset interrupt flag

RIM

#### **Nested interrupt context:**

The symptom does not occur when the interrupts are handled normally, i.e.

#### when:

- The interrupt flag is cleared within its own interrupt routine
- The interrupt flag is cleared within any interrupt routine with higher or identical priority level
- The interrupt flag is cleared in any part of the code while this interrupt is disabled

If these conditions are not met, the symptom can be avoided by implementing the following sequence:

**PUSH CC** 

SIM

reset interrupt flag

POP CC

### 15.1.6 External Interrupt Missed

To avoid any risk of generating a parasitic interrupt, the edge detector is automatically disabled for one clock cycle during an access to either DDR and OR. Any input signal edge during this period will not be detected and will not generate an interrupt.

This case can typically occur if the application refreshes the port configuration registers at intervals during runtime.

## Workaround

The workaround is based on software checking the level on the interrupt pin before and after writing to the PxOR or PxDDR registers. If there is a level change (depending on the sensitivity programmed for this pin) the interrupt routine is invoked using the call instruction with three extra PUSH instructions before executing the interrupt routine (this is to make the call compatible with the IRET instruction at the end of the interrupt service routine).

But detection of the level change does ensure that edge occurs during the critical 1 cycle duration and the interrupt has been missed. This may lead to occurrence of same interrupt twice (one hardware and another with software call).

# 16 IMPORTANT NOTES ON ST72F324B FLASH DEVICES:

With the objective of continuous improvement, ST has developed new ST72F324B devices. These devices are fully compatible with all ROM features and provide an improved price/performance ratio compared to the ST72F324 flash devices.

A summary of the technical improvements is given below.

Refer to separate ST72324B datasheet for the ordering information and full specifications.

## 16.1 Reset Pin Logic levels

In ST72F324B Flash devices, the  $V_{\rm IH}/V_{\rm IL}$  levels for the reset pin are the same as specified for ROM devices

# 16.2 Wake-Up from Active Halt mode using external interrupts

In ST72F324B Flash devices, any external interrupt that capable of waking-up the MCU from Halt mode can also wake-up the MCU from Active Halt mode. Consequently note 1 below Table 8 on page 36 does not apply to 'B' devices.

#### 16.3 PLL Jitter

In ST72F324B Flash devices, PLL clock accuracy is improved and the jitter is the same as specified for ROM devices

## 16.4 Active Halt Power Consumption

In ST72F324B Flash devices, the power consumption in Active Halt mode is specified as 230µA max. See Table 12.5.1 on page 120 for test conditions.

## 16.5 Timer A Registers

In ST72F324B Flash devices, all Timer A registers are present and their functionality is the same as described for ROM devices in the ST72324B datasheet.
