Understanding Embedded - FPGAs (Field Programmable Gate Array)

Embedded - FPGAs, or Field Programmable Gate Arrays, are advanced integrated circuits that offer unparalleled flexibility and performance for digital systems. Unlike traditional fixed-function logic devices, FPGAs can be programmed and reprogrammed to execute a wide array of logical operations, enabling customized functionality tailored to specific applications. This reprogrammability allows developers to iterate designs quickly and implement complex functions without the need for custom hardware.

Applications of Embedded - FPGAs

The versatility of Embedded - FPGAs makes them indispensable in numerous fields. In telecommunications,

Note to Table 1–2:

(1) n = 0, 1, or 2.

Maximum Allowed Overshoot and Undershoot Voltage

During transitions, input signals may overshoot to the voltage shown in Table 1–3 and undershoot to –2.0 V for magnitude of currents less than 100 mA and periods shorter than 20 ns.

Table 1–3 lists the Arria II GX and GZ maximum allowed input overshoot voltage and the duration of the overshoot voltage as a percentage over the device lifetime. The maximum allowed overshoot duration is specified as a percentage of high-time over the lifetime of the device. A DC signal is equivalent to 100% duty cycle. For example, a signal that overshoots to 4.3 V can only be at 4.3 V for 5.41% over the lifetime of the device; for a device lifetime of 10 years, this amounts to 5.41/10ths of a year.

Table 1–6. Recommended Operating Conditions for Arria II GZ Devices *(Note 6)* (Part 2 of 2)

		Industrial	–40	—	100	°C
t_{RAMP}	Power supply ramp time	Normal POR (PORSEL=0)	0.05	—	100	ms
		Fast POR (PORSEL=1)	0.05	—	4	ms

Notes to Table 1–6:

(1) Altera recommends a 3.0-V nominal battery voltage when connecting V_{CCBAT} to a battery for volatile key backup. If you do not use the volatile security key, you may connect the V_{CCBAT} to either GND or a 3.0-V power supply.

(2) V_{CCPD} must be 2.5 V when V_{CCIO} is 2.5, 1.8, 1.5, or 1.2 V. V_{CCPD} must be 3.0 V when V_{CCIO} is 3.0 V.

(3) n = 0, 1, or 2.

(4) $V_{CCA\_L/R}$ must be connected to a 3.0-V supply if the clock multiplier unit (CMU) phase-locked loop (PLL), receiver clock data recovery (CDR), or both, are configured at a base data rate > 4.25 Gbps. For data rates up to 4.25 Gbps, you can connect $V_{CCA\_L/R}$ to either 3.0 V or 2.5 V.

(5) $V_{CCH\_GXBL/R}$ must be connected to a 1.4-V supply if the transmitter channel data rate is > 6.5 Gbps. For data rates up to 6.5 Gbps, you can connect $V_{CCH\_GXBL/R}$ to either 1.4 V or 1.5 V.

(6) Transceiver power supplies do not have power-on-reset (POR) circuitry. After initial power-up, violating the transceiver power supply operating conditions could lead to unpredictable link behavior.

DC Characteristics

This section lists the supply current, I/O pin leakage current, on-chip termination (OCT) accuracy and variation, input pin capacitance, internal weak pull-up and pull-down resistance, hot socketing, and Schmitt trigger input specifications.

Supply Current

Standby current is the current the device draws after the device is configured with no inputs or outputs toggling and no activity in the device. Because these currents vary largely with the resources used, use the Microsoft Excel-based Early Power Estimator (EPE) to get supply current estimates for your design.

For more information about power estimation tools, refer to the *PowerPlay Early Power Estimator User Guide* and the *PowerPlay Power Analysis* chapter.

I/O Pin Leakage Current

Table 1–7 lists the Arria II GX I/O pin leakage current specifications.

Bus Hold

Bus hold retains the last valid logic state after the source driving it either enters the high impedance state or is removed. Each I/O pin has an option to enable bus hold in user mode. Bus hold is always disabled in configuration mode.

Table 1–9 lists bus hold specifications for Arria II GX devices.

f_{DRIFT}	Frequency drift after PFDENA is disabled for duration of 100 us	—	—	±10	%

Notes to Table 1–45:

(1) This specification is limited in the Quartus II software by the I/O maximum frequency. The maximum I/O frequency is different for each I/O standard.

(2) This specification is limited by the lower of the two: I/O F_{MAX} or F_{OUT} of the PLL.

(3) A high input jitter directly affects the PLL output jitter. To have low PLL output clock jitter, you must provide a clean clock source that is less than 120 ps.

(4) F_{REF} is fIN/N when N = 1.

(5) Peak-to-peak jitter with a probability level of 10^{-12} (14 sigma, 99.99999999974404% confidence level). The output jitter specification applies to the intrinsic jitter of the PLL, when an input jitter of 30 ps is applied. The external memory interface clock output jitter specifications use a different measurement method and are available in Table 1–64 on page 1–71.

(6) The cascaded PLL specification is only applicable with the following condition:
a. Upstream PLL: 0.59 Mhz ≤ Upstream PLL BW < 1 MHz
b. Downstream PLL: Downstream PLL BW > 2 MHz

(7) High bandwidth PLL settings are not supported in external feedback mode.

(8) External memory interface clock output jitter specifications use a different measurement method, which is available in Table 1–63 on page 1–71.

Notes to Table 1–54:

(1) When J = 3 to 10, use the SERDES block.

(2) When J = 1 or 2, bypass the SERDES block.

(3) Clock Boost Factor (W) is the ratio between input data rate to the input clock rate.

(4) The minimum specification depends on the clock source (for example, the PLL and clock pin) and the clock routing resource (global, regional, or local) that you use. The I/O differential buffer and input register do not have a minimum toggle rate.

(5) You must calculate the leftover timing margin in the receiver by performing link timing closure analysis. You must consider the board skew margin, transmitter channel-to-channel skew, and receiver sampling margin to determine leftover timing margin.

(6) You can estimate the achievable maximum data rate for non-DPA mode by performing link timing closure analysis. You must consider the board skew margin, transmitter delay margin, and the receiver sampling margin to determine the maximum data rate supported.

(7) This is achieved by using the LVDS and DPA clock network.

(8) If the receiver with DPA enabled and transmitter are using shared PLLs, the minimum data rate is 150 Mbps.

(9) This only applies to DPA and soft-CDR modes.

(10) This only applies to LVDS source synchronous mode.

Table 1–55 lists DPA lock time specifications for Arria II GX and GZ devices.

Table 1–55. DPA Lock Time Specifications for Arria II Devices *(Note 1)*, *(2)*, *(3)*

Miscellaneous	10101010	8	32	640 data transitions
	01010101	8	32	640 data transitions

Notes to Table 1–55:

(1) The DPA lock time is for one channel.

(2) One data transition is defined as a 0-to-1 or 1-to-0 transition.

(3) The DPA lock time stated in the table applies to both commercial and industrial grade.

(4) This is the number of repetitions for the stated training pattern to achieve the 256 data transitions.

Table 1–68. Glossary (Part 3 of 4)

Letter	Subject	Definitions
S	**SW (sampling window)**	The period of time during which the data must be valid in order to capture it correctly. The setup and hold times determine the ideal strobe position within the sampling window: *Timing Diagram* 	Single-ended Voltage Referenced I/O Standard	The JEDEC standard for SSTL and HSTL I/O standards define both the AC and DC input signal values. The AC values indicate the voltage levels at which the receiver must meet its timing specifications. The DC values indicate the voltage levels at which the final logic state of the receiver is unambiguously defined. After the receiver input has crossed the AC value, the receiver changes to the new logic state. The new logic state is then maintained as long as the input stays beyond the AC threshold. This approach is intended to provide predictable receiver timing in the presence of input waveform ringing: *Single-Ended Voltage Referenced I/O Standard* T	**t_C**	High-speed receiver and transmitter input and output clock period.
	TCCS (channel-to-channel-skew)	The timing difference between the fastest and slowest output edges, including t_{CO} variation and clock skew, across channels driven by the same PLL. The clock is included in the TCCS measurement (refer to the *Timing Diagram* figure under **S** in this table).
	t_{DUTY}	High-speed I/O block: Duty cycle on the high-speed transmitter output clock. **Timing Unit Interval (TUI)** The timing budget allowed for skew, propagation delays, and data sampling window. (TUI = 1/(Receiver Input Clock Frequency Multiplication Factor) = t_C/w)
	t_{FALL}	Signal high-to-low transition time (80-20%)
	t_{INCCJ}	Cycle-to-cycle jitter tolerance on the PLL clock input.
	t_{OUTPJ_IO}	Period jitter on the general purpose I/O driven by a PLL.
	t_{OUTPJ_DC}	Period jitter on the dedicated clock output driven by a PLL.
	t_{RISE}	Signal low-to-high transition time (20-80%).
