Understanding Embedded - FPGAs (Field Programmable Gate Array)

Embedded - FPGAs, or Field Programmable Gate Arrays, are advanced integrated circuits that offer unparalleled flexibility and performance for digital systems. Unlike traditional fixed-function logic devices, FPGAs can be programmed and reprogrammed to execute a wide array of logical operations, enabling customized functionality tailored to specific applications. This reprogrammability allows developers to iterate designs quickly and implement complex functions without the need for custom hardware.

Applications of Embedded - FPGAs

The versatility of Embedded - FPGAs makes them indispensable in numerous fields. In telecommunications,

Details

Product Status	Obsolete
Number of LABs/CLBs	9600
Number of Logic Elements/Cells	43200
Total RAM Bits	655360
Number of I/O	512
Number of Gates	2541952
Voltage - Supply	1.71V ~ 1.89V
Mounting Type	Surface Mount
Operating Temperature	-40°C ~ 100°C (TJ)
Package / Case	680-LBGA Exposed Pad
Supplier Device Package	680-FTEBGA (40x40)
Purchase URL	https://www.e-xfl.com/product-detail/xilinx/xcv2000e-7fg680i

the internal storage elements to begin changing state in response to the logic and the user clock.

The relative timing of these events can be changed. In addition, the GTS, GSR, and GWE events can be made dependent on the DONE pins of multiple devices all going High, forcing the devices to start synchronously. The sequence can also be paused at any stage until lock has been achieved on any or all DLLs.

Readback

The configuration data stored in the Virtex-E configuration memory can be readback for verification. Along with the configuration data it is possible to readback the contents all flip-flops/latches, LUT RAMs, and block RAMs. This capability is used for real-time debugging. For more detailed information, see application note XAPP138 "Virtex FPGA Series Configuration and Readback".

Design Considerations

This section contains more detailed design information on the following features.

- Delay-Locked Loop . . . see [page 19](#)
- BlockRAM . . . see [page 24](#)
- SelectI/O . . . see [page 31](#)

Using DLLs

The Virtex-E FPGA series provides up to eight fully digital dedicated on-chip Delay-Locked Loop (DLL) circuits which provide zero propagation delay, low clock skew between output clock signals distributed throughout the device, and advanced clock domain control. These dedicated DLLs can be used to implement several circuits which improve and simplify system level design.

Introduction

As FPGAs grow in size, quality on-chip clock distribution becomes increasingly important. Clock skew and clock delay impact device performance and the task of managing clock skew and clock delay with conventional clock trees becomes more difficult in large devices. The Virtex-E series of devices resolve this potential problem by providing up to eight fully digital dedicated on-chip DLL circuits, which provide zero propagation delay and low clock skew between output clock signals distributed throughout the device.

Each DLL can drive up to two global clock routing networks within the device. The global clock distribution network minimizes clock skews due to loading differences. By monitoring a sample of the DLL output clock, the DLL can compensate for the delay on the routing network, effectively eliminating the delay from the external input port to the individual clock loads within the device.

In addition to providing zero delay with respect to a user source clock, the DLL can provide multiple phases of the source clock. The DLL can also act as a clock doubler or it can divide the user source clock by up to 16.

Clock multiplication gives the designer a number of design alternatives. For instance, a 50 MHz source clock doubled by the DLL can drive an FPGA design operating at 100 MHz. This technique can simplify board design because the clock path on the board no longer distributes such a high-speed signal. A multiplied clock also provides designers the option of time-domain-multiplexing, using one circuit twice per clock cycle, consuming less area than two copies of the same circuit. Two DLLs in can be connected in series to increase the effective clock multiplication factor to four.

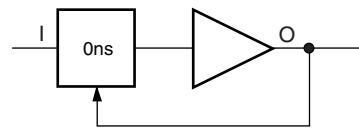

The DLL can also act as a clock mirror. By driving the DLL output off-chip and then back in again, the DLL can be used to deskew a board level clock between multiple devices.

In order to guarantee the system clock establishes prior to the device "waking up," the DLL can delay the completion of the device configuration process until after the DLL achieves lock.

By taking advantage of the DLL to remove on-chip clock delay, the designer can greatly simplify and improve system level design involving high-fanout, high-performance clocks.

Library DLL Symbols

[Figure 21](#) shows the simplified Xilinx library DLL macro symbol, BUFGDLL. This macro delivers a quick and efficient way to provide a system clock with zero propagation delay throughout the device. [Figure 22](#) and [Figure 23](#) show the two library DLL primitives. These symbols provide access to the complete set of DLL features when implementing more complex applications.

ds022_25_121099

[Figure 21: Simplified DLL Macro Symbol BUFGDLL](#)

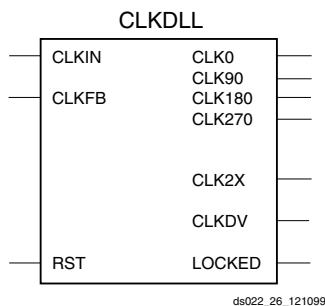

Figure 22: Standard DLL Symbol CLKDLL

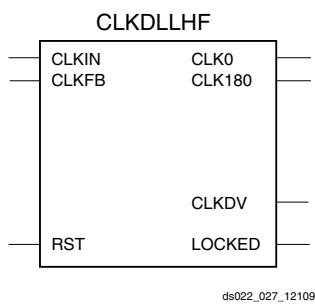

Figure 23: High Frequency DLL Symbol CLKDLLHF

BUFGDLL Pin Descriptions

Use the BUFGDLL macro as the simplest way to provide zero propagation delay for a high-fanout on-chip clock from an external input. This macro uses the IBUFG, CLKDLL and BUFG primitives to implement the most basic DLL application as shown in [Figure 24](#).

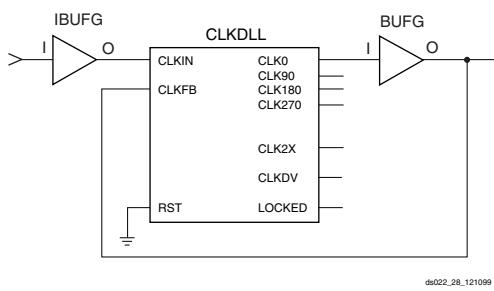

Figure 24: BUFGDLL Schematic

This symbol does not provide access to the advanced clock domain controls or to the clock multiplication or clock division features of the DLL. This symbol also does not provide access to the RST, or LOCKED pins of the DLL. For access to these features, a designer must use the library DLL primitives described in the following sections.

Source Clock Input — I

The I pin provides the user source clock, the clock signal on which the DLL operates, to the BUFGDLL. For the BUFGDLL macro the source clock frequency must fall in the low frequency range as specified in the data sheet. The BUFG-

DLL requires an external signal source clock. Therefore, only an external input port can source the signal that drives the BUFGDLL I pin.

Clock Output — O

The clock output pin O represents a delay-compensated version of the source clock (I) signal. This signal, sourced by a global clock buffer BUFG symbol, takes advantage of the dedicated global clock routing resources of the device.

The output clock has a 50-50 duty cycle unless you deactivate the duty cycle correction property.

CLKDLL Primitive Pin Descriptions

The library CLKDLL primitives provide access to the complete set of DLL features needed when implementing more complex applications with the DLL.

Source Clock Input — CLKIN

The CLKIN pin provides the user source clock (the clock signal on which the DLL operates) to the DLL. The CLKIN frequency must fall in the ranges specified in the data sheet. A global clock buffer (BUFG) driven from another CLKDLL, one of the global clock input buffers (IBUFG), or an IO_LVDS_DLL pin on the same edge of the device (top or bottom) must source this clock signal. There are four IO_LVDS_DLL input pins that can be used as inputs to the DLLs. This makes a total of eight usable input pins for DLLs in the Virtex-E family.

Feedback Clock Input — CLKFB

The DLL requires a reference or feedback signal to provide the delay-compensated output. Connect only the CLK0 or CLK2X DLL outputs to the feedback clock input (CLKFB) pin to provide the necessary feedback to the DLL. The feedback clock input can also be provided through one of the following pins.

IBUFG - Global Clock Input Pad

IO_LVDS_DLL - the pin adjacent to IBUFG

If an IBUFG sources the CLKFB pin, the following special rules apply.

1. An external input port must source the signal that drives the IBUFG I pin.
2. The CLK2X output must feedback to the device if both the CLK0 and CLK2X outputs are driving off chip devices.
3. That signal must directly drive only OBUs and nothing else.

These rules enable the software determine which DLL clock output sources the CLKFB pin.

Reset Input — RST

When the reset pin RST activates the LOCKED signal deactivates within four source clock cycles. The RST pin, active High, must either connect to a dynamic signal or tied to

SSTL2_II

A sample circuit illustrating a valid termination technique for SSTL2_II appears in [Figure 52](#). DC voltage specifications appear in [Table 31](#).

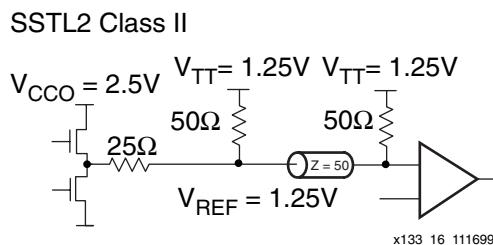

Figure 52: Terminated SSTL2 Class II

Table 31: SSTL2_II Voltage Specifications

Parameter	Min	Typ	Max
V_{CCO}	2.3	2.5	2.7
$V_{REF} = 0.5 \times V_{CCO}$	1.15	1.25	1.35
$V_{TT} = V_{REF} + N^{(1)}$	1.11	1.25	1.39
$V_{IH} = V_{REF} + 0.18$	1.33	1.43	3.0 ⁽²⁾
$V_{IL} = V_{REF} - 0.18$	-0.3 ⁽³⁾	1.07	1.17
$V_{OH} = V_{REF} + 0.8$	1.95	-	-
$V_{OL} = V_{REF} - 0.8$	-	-	0.55
I_{OH} at V_{OH} (mA)	-15.2	-	-
I_{OL} at V_{OL} (mA)	15.2	-	-

Notes:

1. N must be greater than or equal to -0.04 and less than or equal to 0.04.
2. V_{IH} maximum is $V_{CCO} + 0.3$.
3. V_{IL} minimum does not conform to the formula.

CTT

A sample circuit illustrating a valid termination technique for CTT appear in [Figure 53](#). DC voltage specifications appear in [Table 32](#).

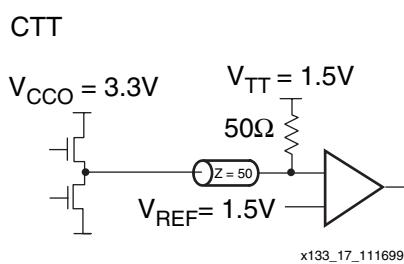

Figure 53: Terminated CTT

Table 32: CTT Voltage Specifications

Parameter	Min	Typ	Max
V_{CCO}	2.05 ⁽¹⁾	3.3	3.6
V_{REF}	1.35	1.5	1.65
V_{TT}	1.35	1.5	1.65
$V_{IH} = V_{REF} + 0.2$	1.55	1.7	-
$V_{IL} = V_{REF} - 0.2$	-	1.3	1.45
$V_{OH} = V_{REF} + 0.4$	1.75	1.9	-
$V_{OL} = V_{REF} - 0.4$	-	1.1	1.25
I_{OH} at V_{OH} (mA)	-8	-	-
I_{OL} at V_{OL} (mA)	8	-	-

Notes:

1. Timing delays are calculated based on V_{CCO} min of 3.0V.

PCI33_3 & PCI66_3

PCI33_3 or PCI66_3 require no termination. DC voltage specifications appear in [Table 33](#).

Table 33: PCI33_3 and PCI66_3 Voltage Specifications

Parameter	Min	Typ	Max
V_{CCO}	3.0	3.3	3.6
V_{REF}	-	-	-
V_{TT}	-	-	-
$V_{IH} = 0.5 \times V_{CCO}$	1.5	1.65	$V_{CCO} + 0.5$
$V_{IL} = 0.3 \times V_{CCO}$	-0.5	0.99	1.08
$V_{OH} = 0.9 \times V_{CCO}$	2.7	-	-
$V_{OL} = 0.1 \times V_{CCO}$	-	-	0.36
I_{OH} at V_{OH} (mA)	Note 1	-	-
I_{OL} at V_{OL} (mA)	Note 1	-	-

Notes:

1. Tested according to the relevant specification.

Table 42: Input Library Macros

IBUFDS_LDPE_LVDS	I, IB, GE, G, PRE	Q

Creating LVDS Output Buffers

LVDS output buffers can be placed in a wide number of IOB locations. The exact locations are dependent on the package used. The Virtex-E package information lists the possible locations as IO_L#P for the P-side and IO_L#N for the N-side, where # is the pair number.

HDL Instantiation

Both output buffers are required to be instantiated in the design and placed on the correct IO_L#P and IO_L#N locations. The IOB must have the same net source the following pins, clock (C), set/reset (SR), output (O), output clock enable (OCE). In addition, the output (O) pins must be inverted with respect to each other, and if output registers are used, the INIT states must be opposite values (one HIGH and one LOW). Failure to follow these rules leads to DRC errors in software.

VHDL Instantiation

```

data0_p : OBDFL_LVDS port map
(I=>data_int(0), O=>data_p(0));

data0_inv: INV      port map
(I=>data_int(0), O=>data_n_int(0));

data0_n : OBDFL_LVDS port map
(I=>data_n_int(0), O=>data_n(0));

```

Verilog Instantiation

```

OBDFL_LVDS data0_p (.I(data_int[0]),
.O(data_p[0]));

INV      data0_inv (.I(data_int[0]),
.O(data_n_int[0]));

OBDFL_LVDS data0_n (.I(data_n_int[0]),
.O(data_n[0]));

```

Location Constraints

All LVDS buffers must be explicitly placed on a device. For the output buffers this can be done with the following constraint in the .ucf or .ncf file.

```

NET data_p<0> LOC = D28; # IO_L0P
NET data_n<0> LOC = B29; # IO_L0N

```

Synchronous vs. Asynchronous Outputs

If the outputs are synchronous (registered in the IOB) then any IO_L#PIN pair can be used. If the outputs are asynchronous (no output register), then they must use one of the pairs that are part of the same IOB group at the end of a ROW or COLUMN in the device.

The LVDS pairs that can be used as asynchronous outputs are listed in the Virtex-E pinout tables. Some pairs are marked as asynchronous-capable for all devices in that package, and others are marked as available only for that device in the package. If the device size might change at some point in the product lifetime, then only the common pairs for all packages should be used.

Adding an Output Register

All LVDS buffers can have an output register in the IOB. The output registers must be in both the P-side and N-side IOBs. All the normal IOB register options are available (FD, FDE, FDC, FDCE, FDP, FDPE, FDR, FDRE, FDS, FDSE, LD, LDE, LDC, LDCE, LDP, LDPE). The register elements can be inferred or explicitly instantiated in the HDL code.

Special care must be taken to insure that the D pins of the registers are inverted and that the INIT states of the registers are opposite. The clock pin (C), clock enable (CE) and set/reset (CLR/PRE or S/R) pins must connect to the same source. Failure to do this leads to a DRC error in the software.

The register elements can be packed in the IOB using the IOB property to TRUE on the register or by using the “map -pr [ilob]” where “i” is inputs only, “o” is outputs only and “b” is both inputs and outputs.

To improve design coding times VHDL and Verilog synthesis macro libraries have been developed to explicitly create these structures. The output library macros are listed in [Table 43](#). The O and OB inputs to the macros are the external net connections.

The register elements can be packed in the IOB using the IOB property to TRUE on the register or by using the “map -pr [ilob]” where “i” is inputs only, “o” is outputs only and “b” is both inputs and outputs.

To improve design coding times VHDL and Verilog synthesis macro libraries have been developed to explicitly create these structures. The input library macros are listed below. The 3-state is configured to be 3-stated at GSR and when the PRE,CLR,S or R is asserted and shares its clock enable with the output register. If this is not desirable then the library can be updated by the user for the desired functionality. The O and OB inputs to the macros are the external net connections.

Creating a LVDS Bidirectional Buffer

LVDS bidirectional buffers can be placed in a wide number of IOB locations. The exact locations are dependent on the package used. The Virtex-E package information lists the possible locations as IO_L#P for the P-side and IO_L#N for the N-side, where # is the pair number.

HDL Instantiation

Both bidirectional buffers are required to be instantiated in the design and placed on the correct IO_L#P and IO_L#N locations. The IOB must have the same net source the following pins, clock (C), set/reset (SR), 3-state (T), 3-state clock enable (TCE), output (O), output clock enable (OCE). In addition, the output (O) pins must be inverted with respect to each other, and if output registers are used, the INIT states must be opposite values (one HIGH and one LOW). If 3-state registers are used, they must be initialized to the same state. Failure to follow these rules leads to DRC errors in the software.

VHDL Instantiation

```
data0_p: IOBUF_LVDS port map
(I=>data_out(0), T=>data_tri,
IO=>data_p(0), O=>data_int(0));
data0_inv: INV      port map
(I=>data_out(0), O=>data_n_out(0));
data0_n : IOBUF_LVDS port map
(I=>data_n_out(0), T=>data_tri,
IO=>data_n(0), O=>open);
```

Verilog Instantiation

```
IOBUF_LVDS data0_p(.I(data_out[0]),
.T(data_tri), .IO(data_p[0]),
.O(data_int[0]);
INV       data0_inv (.I(data_out[0],
.O(data_n_out[0]));
IOBUF_LVDS
data0_n(.I(data_n_out[0]),.T(data_tri),
.IO(data_n[0]).O());
```

Location Constraints

All LVDS buffers must be explicitly placed on a device. For the output buffers this can be done with the following constraint in the .ucf or .ncf file.

```
NET data_p<0> LOC = D28; # IO_L0P
```

```
NET data_n<0> LOC = B29; # IO_L0N
```

Synchronous vs. Asynchronous Bidirectional Buffers

If the output side of the bidirectional buffers are synchronous (registered in the IOB), then any IO_L#PIN pair can be used. If the output side of the bidirectional buffers are asynchronous (no output register), then they must use one of the pairs that is a part of the asynchronous LVDS IOB group. This applies for either the 3-state pin or the data out pin.

The LVDS pairs that can be used as asynchronous bidirectional buffers are listed in the Virtex-E pinout tables. Some pairs are marked as asynchronous capable for all devices in that package, and others are marked as available only for that device in the package. If the device size might change at some point in the product's lifetime, then only the common pairs for all packages should be used.

Adding Output and 3-State Registers

All LVDS buffers can have an output and input registers in the IOB. The output registers must be in both the P-side and N-side IOBs, the input register is only in the P-side. All the normal IOB register options are available (FD, FDE, FDC, FDCE, FDP, FDPE, FDR, FDRE, FDS, FDSE, LD, LDE, LDC, LDCE, LDP, LDPE). The register elements can be inferred or explicitly instantiated in the HDL code. Special care must be taken to insure that the D pins of the registers are inverted and that the INIT states of the registers are opposite. The 3-state (T), 3-state clock enable (CE), clock pin (C), output clock enable (CE), and set/reset (CLR/PRE or S/R) pins must connect to the same source. Failure to do this leads to a DRC error in the software.

The register elements can be packed in the IOB using the IOB property to TRUE on the register or by using the “map -pr [ilob]” where “i” is inputs only, “o” is outputs only and “b” is both inputs and outputs. To improve design coding times VHDL and Verilog synthesis macro libraries have been developed to explicitly create these structures. The bidirectional I/O library macros are listed in [Table 44](#). The 3-state is configured to be 3-stated at GSR and when the PRE,CLR,S or R is asserted and shares its clock enable with the output and input register. If this is not desirable then the library can be updated by the user for the desired functionality. The I/O and IOB inputs to the macros are the external net connections.

Virtex-E Switching Characteristics

All devices are 100% functionally tested. Internal timing parameters are derived from measuring internal test patterns. Listed below are representative values. For more specific, more precise, and worst-case guaranteed data, use the values reported by the static timing analyzer (TRCE in the Xilinx Development System) and back-annotated to the simulation net list. All timing parameters assume worst-case operating conditions (supply voltage and junction temperature). Values apply to all Virtex-E devices unless otherwise noted.

IOB Input Switching Characteristics

Input delays associated with the pad are specified for LVTTL levels in [Table 2](#). For other standards, adjust the delays with the values shown in [IOB Input Switching Characteristics Standard Adjustments](#), page 8.

Table 2: IOB Input Switching Characteristics

			Speed Grade ⁽¹⁾				Units
Description ⁽²⁾	Symbol	Device	Min	-8	-7	-6	
Propagation Delays							
Pad to I output, no delay	T _{IOPI}	All	0.43	0.8	0.8	0.8

Note 1: NC in the XCV200E device.

FG456 Differential Pin Pairs

Virtex-E devices have differential pin pairs that can also provide other functions when not used as a differential pair. A √ in the AO column indicates that the pin pair can be used as an asynchronous output for all devices provided in this package. Pairs with a note number in the AO column are device dependent. They can have asynchronous outputs if the pin pair are in the same CLB row and column in the device. Numbers in this column refer to footnotes that indicate which devices have pin pairs than can be asynchronous outputs. The Other Functions column indicates alternative function(s) not available when the pair is used as a differential pair or differential clock.
