Understanding [Embedded - FPGAs \(Field Programmable Gate Array\)](#)

Embedded - FPGAs, or Field Programmable Gate Arrays, are advanced integrated circuits that offer unparalleled flexibility and performance for digital systems. Unlike traditional fixed-function logic devices, FPGAs can be programmed and reprogrammed to execute a wide array of logical operations, enabling customized functionality tailored to specific applications. This reprogrammability allows developers to iterate designs quickly and implement complex functions without the need for custom hardware.

Applications of Embedded - FPGAs

The versatility of Embedded - FPGAs makes them indispensable in numerous fields. In telecommunications,

Details

Product Status	Obsolete
Number of LABs/CLBs	9600
Number of Logic Elements/Cells	43200
Total RAM Bits	655360
Number of I/O	660
Number of Gates	2541952
Voltage - Supply	1.71V ~ 1.89V
Mounting Type	Surface Mount
Operating Temperature	0°C ~ 85°C (TJ)
Package / Case	860-BGA Exposed Pad
Supplier Device Package	860-FBGA (42.5x42.5)
Purchase URL	https://www.e-xfl.com/product-detail/xilinx/xcv2000e-7fg860c

Table 1: Virtex-E Field-Programmable Gate Array Family Members

Device	System Gates	Logic Gates	CLB Array	Logic Cells	Differential I/O Pairs	User I/O	BlockRAM Bits	Distributed RAM Bits

Virtex-E Compared to Virtex Devices

The Virtex-E family offers up to 43,200 logic cells in devices up to 30% faster than the Virtex family.

I/O performance is increased to 622 Mb/s using Source Synchronous data transmission architectures and synchronous system performance up to 240 MHz using singled-ended SelectI/O technology. Additional I/O standards are supported, notably LVPECL, LVDS, and BLVDS, which use two pins per signal. Almost all signal pins can be used for these new standards.

Virtex-E devices have up to 640 Kb of faster (250 MHz) block SelectRAM, but the individual RAMs are the same size and structure as in the Virtex family. They also have eight DLLs instead of the four in Virtex devices. Each individual DLL is slightly improved with easier clock mirroring and 4x frequency multiplication.

V_{CCINT} , the supply voltage for the internal logic and memory, is 1.8 V, instead of 2.5 V for Virtex devices. Advanced processing and 0.18 μ m design rules have resulted in smaller dice, faster speed, and lower power consumption.

I/O pins are 3 V tolerant, and can be 5 V tolerant with an external 100 Ω resistor. PCI 5 V is not supported. With the addition of appropriate external resistors, any pin can tolerate any voltage desired.

Banking rules are different. With Virtex devices, all input buffers are powered by V_{CCINT} . With Virtex-E devices, the LVTTL, LVCMSO2, and PCI input buffers are powered by the I/O supply voltage V_{CCO} .

The Virtex-E family is not bitstream-compatible with the Virtex family, but Virtex designs can be compiled into equivalent Virtex-E devices.

The same device in the same package for the Virtex-E and Virtex families are pin-compatible with some minor exceptions. See the data sheet pinout section for details.

General Description

The Virtex-E FPGA family delivers high-performance, high-capacity programmable logic solutions. Dramatic increases in silicon efficiency result from optimizing the new architecture for place-and-route efficiency and exploiting an aggressive 6-layer metal 0.18 μ m CMOS process. These advances make Virtex-E FPGAs powerful and flexible alternatives to mask-programmed gate arrays. The Virtex-E family includes the nine members in Table 1.

Building on experience gained from Virtex FPGAs, the Virtex-E family is an evolutionary step forward in programmable logic design. Combining a wide variety of programmable system features, a rich hierarchy of fast, flexible interconnect resources, and advanced process technology, the Virtex-E family delivers a high-speed and high-capacity programmable logic solution that enhances design flexibility while reducing time-to-market.

Virtex-E Architecture

Virtex-E devices feature a flexible, regular architecture that comprises an array of configurable logic blocks (CLBs) surrounded by programmable input/output blocks (IOBs), all interconnected by a rich hierarchy of fast, versatile routing

Table 9 lists the total number of bits required to configure each device.

Table 9: Virtex-E Bitstream Lengths

Device	# of Configuration Bits
XCV50E	630,048
XCV100E	863,840
XCV200E	1,442,016
XCV300E	1,875,648
XCV400E	2,693,440
XCV600E	3,961,632
XCV1000E	6,587,520
XCV1600E	8,308,992
XCV2000E	10,159,648
XCV2600E	12,922,336
XCV3200E	16,283,712

Slave-Serial Mode

In slave-serial mode, the FPGA receives configuration data in bit-serial form from a serial PROM or other source of serial configuration data. The serial bitstream must be set up at the DIN input pin a short time before each rising edge of an externally generated CCLK.

For more detailed information on serial PROMs, see the PROM data sheet at <http://www.xilinx.com/bvdocs/publications/ds026.pdf>.

Multiple FPGAs can be daisy-chained for configuration from a single source. After a particular FPGA has been configured, the data for the next device is routed to the DOUT pin. The maximum capacity for a single LOUT/DOUT write is $2^{20} \cdot 1$ (1,048,575) 32-bit words, or 33,554,4000 bits. The data on the DOUT pin changes on the rising edge of CCLK.

The change of DOUT on the rising edge of CCLK differs from previous families, but does not cause a problem for mixed configuration chains. This change was made to improve serial configuration rates for Virtex and Virtex-E only chains.

Figure 13 shows a full master/slave system. A Virtex-E device in slave-serial mode should be connected as shown in the right-most device.

Slave-serial mode is selected by applying <111> or <011> to the mode pins (M2, M1, M0). A weak pull-up on the mode pins makes slave serial the default mode if the pins are left unconnected. However, it is recommended to drive the configuration mode pins externally. **Figure 14** shows slave-serial mode programming switching characteristics.

Table 10 provides more detail about the characteristics shown in **Figure 14**. Configuration must be delayed until the INIT pins of all daisy-chained FPGAs are High.

Table 10: Master/Slave Serial Mode Programming Switching

	Description	Figure References	Symbol	Values	Units
CCLK	DIN setup/hold, slave mode	1/2	T_{DCC}/T_{CCD}	5.0 / 0.0	ns, min
	DIN setup/hold, master mode	1/2	T_{DSCK}/T_{CKDS}	5.0 / 0.0	ns, min
	DOUT	3	T_{CCO}	12.0	ns, max
	High time	4	T_{CCH}	5.0	ns, min
	Low time	5	T_{CCL}	5.0	ns, min
	Maximum Frequency		F_{cc}	66	MHz, max
	Frequency Tolerance, master mode with respect to nominal			+45% –30%	

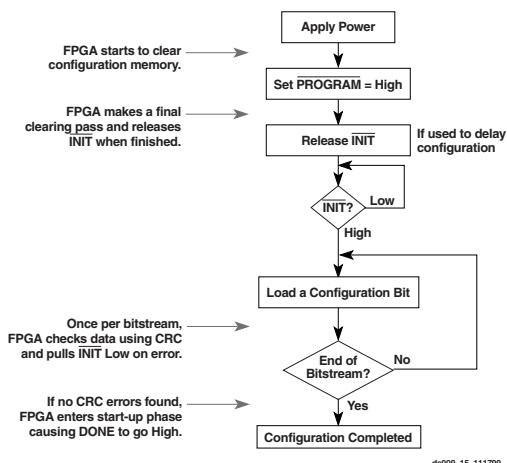

Figure 15: Serial Configuration Flowchart

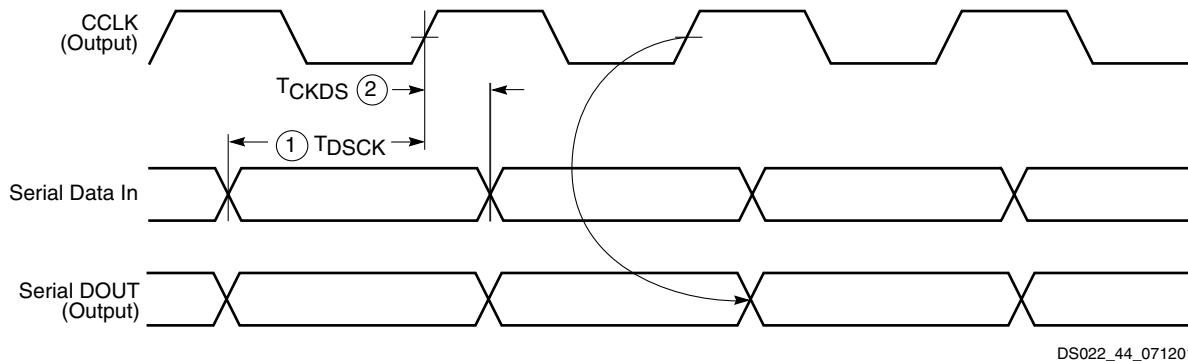

Figure 16: Master-Serial Mode Programming Switching Characteristics

At power-up, V_{CC} must rise from 1.0 V to V_{CC} Min in less than 50 ms, otherwise delay configuration by pulling PROGRAM Low until V_{CC} is valid.

SelectMAP Mode

The SelectMAP mode is the fastest configuration option. Byte-wide data is written into the FPGA with a BUSY flag controlling the flow of data.

An external data source provides a byte stream, CCLK, a Chip Select (\overline{CS}) signal and a Write signal (\overline{WRITE}). If BUSY is asserted (High) by the FPGA, the data must be held until BUSY goes Low.

Data can also be read using the SelectMAP mode. If \overline{WRITE} is not asserted, configuration data is read out of the FPGA as part of a readback operation.

After configuration, the pins of the SelectMAP port can be used as additional user I/O. Alternatively, the port can be retained to permit high-speed 8-bit readback.

Retention of the SelectMAP port is selectable on a design-by-design basis when the bitstream is generated. If retention is selected, PROHIBIT constraints are required to prevent the SelectMAP-port pins from being used as user I/O.

Figure 16 shows the timing of master-serial configuration. Master-serial mode is selected by a <000> or <100> on the mode pins (M2, M1, M0). Table 10 shows the timing information for Figure 16.

Multiple Virtex-E FPGAs can be configured using the SelectMAP mode, and be made to start-up simultaneously. To configure multiple devices in this way, wire the individual CCLK, Data, \overline{WRITE} , and BUSY pins of all the devices in parallel. The individual devices are loaded separately by asserting the \overline{CS} pin of each device in turn and writing the appropriate data. See Table 11 for SelectMAP Write Timing Characteristics.

Write

Write operations send packets of configuration data into the FPGA. The sequence of operations for a multi-cycle write operation is shown below. Note that a configuration packet can be split into many such sequences. The packet does not have to complete within one assertion of \overline{CS} , illustrated in Figure 17.

1. Assert \overline{WRITE} and \overline{CS} Low. Note that when \overline{CS} is asserted on successive CCLKs, \overline{WRITE} must remain either asserted or de-asserted. Otherwise, an abort is initiated, as described below.
2. Drive data onto D[7:0]. Note that to avoid contention, the data source should not be enabled while \overline{CS} is Low and \overline{WRITE} is High. Similarly, while \overline{WRITE} is High, no more than one \overline{CS} should be asserted.

the internal storage elements to begin changing state in response to the logic and the user clock.

The relative timing of these events can be changed. In addition, the GTS, GSR, and GWE events can be made dependent on the DONE pins of multiple devices all going High, forcing the devices to start synchronously. The sequence can also be paused at any stage until lock has been achieved on any or all DLLs.

Readback

The configuration data stored in the Virtex-E configuration memory can be readback for verification. Along with the configuration data it is possible to readback the contents all flip-flops/latches, LUT RAMs, and block RAMs. This capability is used for real-time debugging. For more detailed information, see application note XAPP138 "Virtex FPGA Series Configuration and Readback".

Design Considerations

This section contains more detailed design information on the following features.

- Delay-Locked Loop . . . see [page 19](#)
- BlockRAM . . . see [page 24](#)
- SelectI/O . . . see [page 31](#)

Using DLLs

The Virtex-E FPGA series provides up to eight fully digital dedicated on-chip Delay-Locked Loop (DLL) circuits which provide zero propagation delay, low clock skew between output clock signals distributed throughout the device, and advanced clock domain control. These dedicated DLLs can be used to implement several circuits which improve and simplify system level design.

Introduction

As FPGAs grow in size, quality on-chip clock distribution becomes increasingly important. Clock skew and clock delay impact device performance and the task of managing clock skew and clock delay with conventional clock trees becomes more difficult in large devices. The Virtex-E series of devices resolve this potential problem by providing up to eight fully digital dedicated on-chip DLL circuits, which provide zero propagation delay and low clock skew between output clock signals distributed throughout the device.

Each DLL can drive up to two global clock routing networks within the device. The global clock distribution network minimizes clock skews due to loading differences. By monitoring a sample of the DLL output clock, the DLL can compensate for the delay on the routing network, effectively eliminating the delay from the external input port to the individual clock loads within the device.

In addition to providing zero delay with respect to a user source clock, the DLL can provide multiple phases of the source clock. The DLL can also act as a clock doubler or it can divide the user source clock by up to 16.

Clock multiplication gives the designer a number of design alternatives. For instance, a 50 MHz source clock doubled by the DLL can drive an FPGA design operating at 100 MHz. This technique can simplify board design because the clock path on the board no longer distributes such a high-speed signal. A multiplied clock also provides designers the option of time-domain-multiplexing, using one circuit twice per clock cycle, consuming less area than two copies of the same circuit. Two DLLs in can be connected in series to increase the effective clock multiplication factor to four.

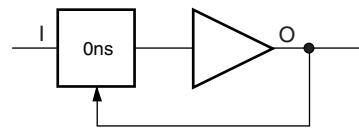

The DLL can also act as a clock mirror. By driving the DLL output off-chip and then back in again, the DLL can be used to deskew a board level clock between multiple devices.

In order to guarantee the system clock establishes prior to the device "waking up," the DLL can delay the completion of the device configuration process until after the DLL achieves lock.

By taking advantage of the DLL to remove on-chip clock delay, the designer can greatly simplify and improve system level design involving high-fanout, high-performance clocks.

Library DLL Symbols

[Figure 21](#) shows the simplified Xilinx library DLL macro symbol, BUFGDLL. This macro delivers a quick and efficient way to provide a system clock with zero propagation delay throughout the device. [Figure 22](#) and [Figure 23](#) show the two library DLL primitives. These symbols provide access to the complete set of DLL features when implementing more complex applications.

Port Signals

Each block SelectRAM+ port operates independently of the others while accessing the same set of 4096 memory cells.

Table 15 describes the depth and width aspect ratios for the block SelectRAM+ memory.

Table 15: Block SelectRAM+ Port Aspect Ratios

Width	Depth	ADDR Bus	Data Bus
1	4096	ADDR<11:0>	DATA<0>
2	2048	ADDR<10:0>	DATA<1:0>
4	1024	ADDR<9:0>	DATA<3:0>
8	512	ADDR<8:0>	DATA<7:0>
16	256	ADDR<7:0>	DATA<15:0>

Clock—CLK[A/B]

Each port is fully synchronous with independent clock pins. All port input pins have setup time referenced to the port CLK pin. The data output bus has a clock-to-out time referenced to the CLK pin.

Enable—EN[A/B]

The enable pin affects the read, write and reset functionality of the port. Ports with an inactive enable pin keep the output pins in the previous state and do not write data to the memory cells.

Write Enable—WE[A/B]

Activating the write enable pin allows the port to write to the memory cells. When active, the contents of the data input bus are written to the RAM at the address pointed to by the address bus, and the new data also reflects on the data out bus. When inactive, a read operation occurs and the contents of the memory cells referenced by the address bus reflect on the data out bus.

Reset—RST[A/B]

The reset pin forces the data output bus latches to zero synchronously. This does not affect the memory cells of the RAM and does not disturb a write operation on the other port.

Address Bus—ADDR[A/B]<#:0>

The address bus selects the memory cells for read or write. The width of the port determines the required width of this bus as shown in Table 15.

Data In Bus—DI[A/B]<#:0>

The data in bus provides the new data value to be written into the RAM. This bus and the port have the same width, as shown in Table 15.

indicating that the block SelectRAM+ memory is now disabled. The DO bus retains the last value.

Dual Port Timing

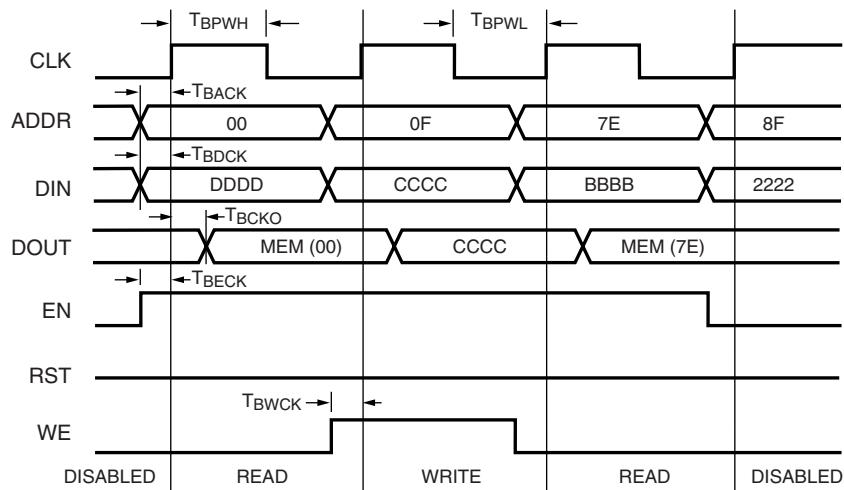

Figure 34 shows a timing diagram for a true dual-port read/write block SelectRAM+ memory. The clock on port A has a longer period than the clock on Port B. The timing parameter T_{BCCS} , (clock-to-clock set-up) is shown on this diagram. The parameter, T_{BCCS} is violated once in the diagram. All other timing parameters are identical to the single port version shown in **Figure 33**.

T_{BCCS} is only of importance when the address of both ports are the same and at least one port is performing a write operation. When the clock-to-clock set-up parameter is violated for a WRITE-WRITE condition, the contents of the memory at that location are invalid. When the clock-to-clock set-up parameter is violated for a WRITE-READ condition,

the contents of the memory are correct, but the read port has invalid data.

At the first rising edge of the CLKA, memory location 0x00 is to be written with the value 0xAAAA and is mirrored on the DOA bus. The last operation of Port B was a read to the same memory location 0x00. The DOB bus of Port B does not change with the new value on Port A, and retains the last read value. A short time later, Port B executes another read to memory location 0x00, and the DOB bus now reflects the new memory value written by Port A.

At the second rising edge of CLKA, memory location 0x7E is written with the value 0x9999 and is mirrored on the DOA bus. Port B then executes a read operation to the same memory location without violating the T_{BCCS} parameter and the DOB reflects the new memory values written by Port A.

ds022_0343_121399

Figure 33: Timing Diagram for Single Port Block SelectRAM+ Memory

LVTTL 3-state output buffers have selectable drive strengths.

The format for LVTTL OBUFT symbol names is as follows:

OBUFT_<slew_rate>_<drive_strength>

where <slew_rate> is either F (Fast) or S (Slow), and <drive_strength> is specified in millamps (2, 4, 6, 8, 12, 16, or 24).

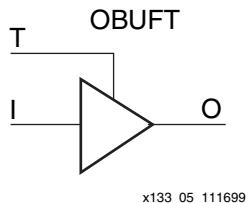

Figure 41: 3-State Output Buffer Symbol (OBUFT)

The following list details variations of the OBUFT symbol.

- OBUFT
- OBUFT_S_2
- OBUFT_S_4
- OBUFT_S_6
- OBUFT_S_8
- OBUFT_S_12
- OBUFT_S_16
- OBUFT_S_24
- OBUFT_F_2
- OBUFT_F_4
- OBUFT_F_6
- OBUFT_F_8
- OBUFT_F_12
- OBUFT_F_16
- OBUFT_F_24
- OBUFT_LVCMOS2
- OBUFT_PCI33_3
- OBUFT_PCI66_3
- OBUFT_GTL
- OBUFT_GTL_P
- OBUFT_HSTL_I
- OBUFT_HSTL_III
- OBUFT_HSTL_IV
- OBUFT_SSTL3_I
- OBUFT_SSTL3_II
- OBUFT_SSTL2_I
- OBUFT_SSTL2_II
- OBUFT_CTT
- OBUFT_AG
- OBUFT_LVCMOS18
- OBUFT_LVDS
- OBUFT_LVPECL

The Virtex-E series supports eight banks for the HQ and PQ packages. The CS package supports four V_{CCO} banks.

The SelectI/O OBUFT placement restrictions require that within a given V_{CCO} bank each OBUFT share the same output source drive voltage. Input buffers of any type and output buffers that do not require V_{CCO} can be placed within the same V_{CCO} bank.

The LOC property can specify a location for the OBUFT.

3-state output buffers and bidirectional buffers can have either a weak pull-up resistor, a weak pull-down resistor, or a weak “keeper” circuit. Control this feature by adding the appropriate symbol to the output net of the OBUFT (PULLUP, PULLDOWN, or KEEPER).

The weak “keeper” circuit requires the input buffer within the IOB to sample the I/O signal. So, OBUFTs programmed for an I/O standard that requires a V_{REF} have automatic placement of a V_{REF} in the bank with an OBUFT configured with a weak “keeper” circuit. This restriction does not affect most circuit design as applications using an OBUFT configured with a weak “keeper” typically implement a bidirectional I/O. In this case the IBUF (and the corresponding V_{REF}) are explicitly placed.

The LOC property can specify a location for the OBUFT.

IOBUF

Use the IOBUF symbol for bidirectional signals that require both an input buffer and a 3-state output buffer with an active high 3-state pin. The generic input/output buffer IOBUF appears in Figure 42.

The extension to the base name defines which I/O standard the IOBUF uses. With no extension specified for the generic IOBUF symbol, the assumed standard is LVTTL input buffer and slew rate limited LVTTL with 12 mA drive strength for the output buffer.

The LVTTL IOBUF additionally can support one of two slew rate modes to minimize bus transients. By default, the slew rate for each output buffer is reduced to minimize power bus transients when switching non-critical signals.

LVTTL bidirectional buffers have selectable output drive strengths.

The format for LVTTL IOBUF symbol names is as follows:

IOBUF_<slew_rate>_<drive_strength>

where <slew_rate> is either F (Fast) or S (Slow), and <drive_strength> is specified in millamps (2, 4, 6, 8, 12, 16, or 24).

Table 21: Guidelines for Max Number of Simultaneously Switching Outputs per Power/Ground Pair (Continued)

Standard	Package		
	BGA, CS, FGA	HQ	PQ, TQ
HSTL Class I	18	13	9
HSTL Class III	9	7	5
HSTL Class IV	5	4	3
SSTL2 Class I	15	11	8
SSTL2 Class II	10	7	5
SSTL3 Class I	11	8	6
SSTL3 Class II	7	5	4
CTT	14	10	7
AGP	9	7	5

Note: This analysis assumes a 35 pF load for each output.

Table 22: Virtex-E Equivalent Power/Ground Pairs

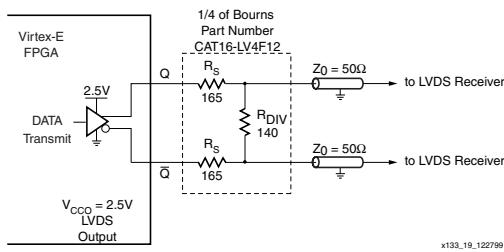

Pkg/Part	XCV100E	XCV200E	XCV300E	XCV400E	XCV600E	XCV1000E	XCV1600E	XCV2000E
CS144	12	12						
PQ240	20	20	20	20				
HQ240					20	20

FG680 ⁽²⁾					46	56	56	56
FG860						58	60	64
FG900					56	58		60
FG1156						96	104	120

Notes:

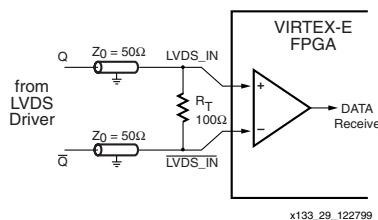

1. Virtex-E devices in FG256 packages have more V_{CCO} than Virtex series devices.
2. FG680 numbers are preliminary.

LVDS

Depending on whether the device is transmitting an LVDS signal or receiving an LVDS signal, there are two different circuits used for LVDS termination. A sample circuit illustrating a valid termination technique for transmitting LVDS signals appears in [Figure 54](#). A sample circuit illustrating a valid termination for receiving LVDS signals appears in [Figure 55](#). [Table 38](#) lists DC voltage specifications. Further information on the specific termination resistor packs shown can be found on [Table 40](#).

[Figure 54: Transmitting LVDS Signal Circuit](#)

V _{OCM} ⁽¹⁾	1.125	1.25	1.375
V _{IDIFF} ⁽¹⁾	0.1	0.35	-
V _{ODIFF} ⁽¹⁾	0.25	0.35	0.45
V _{OH} ⁽¹⁾	1.25	-	-
V _{OL} ⁽¹⁾	-	-	1.25

Notes:

1. Measured with a 100 Ω resistor across Q and \bar{Q} .
2. Measured with a differential input voltage = $+/- 350$ mV.

LVPECL

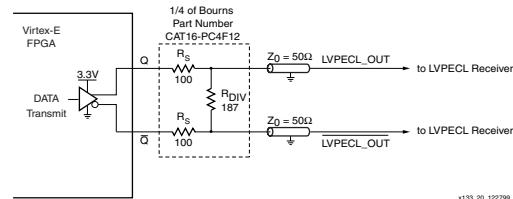

Depending on whether the device is transmitting or receiving an LVPECL signal, two different circuits are used for LVPECL termination. A sample circuit illustrating a valid termination technique for transmitting LVPECL signals appears in [Figure 56](#). A sample circuit illustrating a valid termination for receiving LVPECL signals appears in [Figure 57](#). [Table 39](#) lists DC voltage specifications. Further information on the specific termination resistor packs shown can be found on [Table 40](#).

[Table 39: LVPECL Voltage Specifications](#)

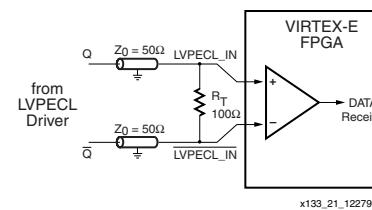

Parameter	Min	Typ	Max
V _{CCO}	3.0	3.3	3.6

Revision History

The following table shows the revision history for this document.

Date	Version	Revision
12/7/99	1.0	Initial Xilinx release.
1/10/00	1.1	Re-released with spd.txt v. 1.18, FG860/900/1156 package information, and additional DLL, Select RAM and SelectI/O information.
1/28/00	1.2	Added Delay Measurement Methodology table, updated SelectI/O section, Figures 30, 54, & 55, text explaining Table 5, T_{BYP} values, buffered Hex Line info, p. 8, I/O Timing Measurement notes, notes for Tables 15, 16, and corrected F1156 pinout table footnote references.
2/29/00	1.3	Updated pinout tables, V_{CC} page 20, and corrected Figure 20.
5/23/00	1.4	Correction to table on p. 22.
7/10/00	1.5	<ul style="list-style-type: none"> • Numerous minor edits. • Data sheet upgraded to Preliminary. • Preview -8 numbers added to Virtex-E Electrical Characteristics tables.
8/1/00	1.6	<ul style="list-style-type: none"> • Reformatted entire document to follow new style guidelines. • Changed speed grade values in tables on pages 35-37.

Global Clock Set-Up and Hold for LVTTL Standard, *without DLL*

Description ⁽¹⁾	Symbol	Device	Speed Grade ^(2, 3)				Units
			Min	-8	-7	-6	
Input Setup and Hold Time Relative to Global Clock Input Signal for LVTTL Standard. For data input with different standards, adjust the setup time delay by the values shown in IOB Input Switching Characteristics Standard Adjustments , page 8.							
Full Delay Global Clock and IFF, without DLL	T_{PSFD}/T_{PHFD}	XCV50E	1.8 / 0	1.8 / 0	1.8 / 0	1.8 / 0	ns
		XCV100E	1.8 / 0	1.8 / 0	1.8 / 0	1.8 / 0	ns
		XCV200E	1.9 / 0	1.9 / 0	1.9 / 0	1.9 / 0	ns
		XCV300E	2.0 / 0	2.0 / 0	2.0 / 0	2.0 / 0	ns
		XCV400E	2.0 / 0	2.0 / 0	2.0 / 0	2.0 / 0	ns
		XCV600E	2.1 / 0	2.1 / 0	2.1 / 0	2.1 / 0	ns
		XCV1000E	2.3 / 0	2.3 / 0	2.3 / 0	2.3 / 0	ns
		XCV1600E	2.5 / 0	2.5 / 0	2.5 / 0	2.5 / 0	ns
		XCV2000E	2.5 / 0	2.5 / 0	2.5 / 0	2.5 / 0	ns
		XCV2600E	2.7 / 0	2.7 / 0	2.7 / 0	2.7 / 0	ns
		XCV3200E	2.8 / 0	2.8 / 0	2.8 / 0	2.8 / 0	ns

Notes:

1. IFF = Input Flip-Flop or Latch
2. Setup time is measured relative to the Global Clock input signal with the fastest route and the lightest load. Hold time is measured relative to the Global Clock input signal with the slowest route and heaviest load.
3. A Zero "0" Hold Time listing indicates no hold time or a negative hold time. Negative values can not be guaranteed "best-case", but if a "0" is listed, there is no positive hold time.

BG432 Differential Pin Pairs

Virtex-E devices have differential pin pairs that can also provide other functions when not used as a differential pair. A √ in the AO column indicates that the pin pair can be used as an asynchronous output for all devices provided in this package. Pairs with a note number in the AO column are device dependent. They can have asynchronous outputs if the pin pair are in the same CLB row and column in the device. Numbers in this column refer to footnotes that indicate which devices have pin pairs than can be asynchronous outputs. The Other Functions column indicates alternative function(s) not available when the pair is used as a differential pair or differential clock.
