
Welcome to E-XFL.COM

What is "Embedded - Microcontrollers"?

"Embedded - Microcontrollers" refer to small, integrated circuits designed to perform specific tasks within larger systems. These microcontrollers are essentially compact computers on a single chip, containing a processor core, memory, and programmable input/output peripherals. They are called "embedded" because they are embedded within electronic devices to control various functions, rather than serving as standalone computers. Microcontrollers are crucial in modern electronics, providing the intelligence and control needed for a wide range of applications.

Applications of "Embedded - Microcontrollers"

Details	
Product Status	Active
Core Processor	PIC
Core Size	16-Bit
Speed	32MHz
Connectivity	I²C, IrDA, LINbus, SPI, UART/USART
Peripherals	Brown-out Detect/Reset, LVD, POR, PWM, WDT
Number of I/O	37
Program Memory Size	8KB (2.75K x 24)
Program Memory Type	FLASH
EEPROM Size	512 x 8
RAM Size	2K x 8
Voltage - Supply (Vcc/Vdd)	2V ~ 5V
Data Converters	A/D 22x10b/12b; D/A 2x8b
Oscillator Type	Internal
Operating Temperature	-40°C ~ 85°C (TA)
Mounting Type	Surface Mount
Package / Case	44-TQFP
Supplier Device Package	44-TQFP (10x10)
Purchase URL	https://www.e-xfl.com/product-detail/microchip-technology/pic24fv08km204-i-pt

TABLE 1-3: DEVICE FEATURES FOR THE PIC24FV16KM204 FAMILY

Features	PIC24FV16KM204	PIC24FV08KM204	PIC24FV16KM202	PIC24FV08KM202
Operating Frequency	DC-32 MHz			
Program Memory (bytes)	16K	8K	16K	8K
Program Memory (instructions)	5632	2816	5632	2816
Data Memory (bytes)	2048			
Data EEPROM Memory (bytes)	512			
Interrupt Sources (soft vectors/NMI traps)	40 (36/4)			
Voltage Range	2.0-5.5V			
I/O Ports	PORTA<11:7,5:0> PORTB<15:0> PORTC<9:0>		PORTA<7,5:0> PORTB<15:0>	
Total I/O Pins	37		23	
Timers	11 (One 16-bit timer, five MCCPs/SCCPs with up to two 16/32 timers each)			
Capture/Compare/PWM modules MCCP SCCP	 3 2			
Serial Communications MSSP UART	 2 2			
Input Change Notification Interrupt	36		22	
12-Bit Analog-to-Digital Module (input channels)	22		19	
Analog Comparators	3			
8-Bit Digital-to-Analog Converters	2			
Operational Amplifiers	2			
Charge Time Measurement Unit (CTMU)	Yes			
Real-Time Clock and Calendar (RTCC)	Yes			
Configurable Logic Cell (CLC)	2			
Resets (and delays)	POR, BOR, RESET Instruction, $\overline{\text{MCLR}}$, WDT, Illegal Opcode, REPEAT Instruction, Hardware Traps, Configuration Word Mismatch (PWRT, OST, PLL Lock)			
Instruction Set	76 Base Instructions, Multiple Addressing Mode Variations			
Packages	44-Pin QFN/TQFP, 48-Pin UQFN		28-Pin SPDIP/SSOP/SOIC/QFN

Legend: x = unknown, u = unchanged, — = unimplemented, q = value depends on condition, r = reserved.
Note 1: These bits are not available on the PIC24F(V)08KM101 device, read as '0'.

7.1 Clock Source Selection at Reset

If clock switching is enabled, the system clock source at device Reset is chosen, as shown in Table 7-2. If clock switching is disabled, the system clock source is always selected according to the Oscillator Configuration bits. For more information, see **Section 9.0 "Oscillator Configuration"**.

TABLE 7-2: OSCILLATOR SELECTION vs. TYPE OF RESET (CLOCK SWITCHING ENABLED)

Reset Type	Clock Source Determinant
POR	FNOSC<2:0> Configuration bits (FOSCSEL<2:0>)
BOR	
$\overline{\text{MCLR}}$	COSC<2:0> Control bits (OSCCON<14:12>)
WDTO	
SWR	

7.2 Device Reset Times

The Reset times for various types of device Reset are summarized in Table 7-3. Note that the system Reset signal, $\overline{\text{SYSRST}}$, is released after the POR and PWRT delay times expire.

The time at which the device actually begins to execute code will also depend on the system oscillator delays, which include the Oscillator Start-up Timer (OST) and the PLL lock time. The OST and PLL lock times occur in parallel with the applicable $\overline{\text{SYSRST}}$ delay times.

The FSCM delay determines the time at which the FSCM begins to monitor the system clock source after the $\overline{\text{SYSRST}}$ signal is released.

TABLE 7-3: RESET DELAY TIMES FOR VARIOUS DEVICE RESETS

Reset Type	Clock Source	$\overline{\text{SYSRST}}$ Delay	System Clock Delay	Notes
POR(6)	EC	TPOR + TPWRT	—	1, 2
	FRC, FRCDIV	TPOR + TPWRT	TFRC	1, 2, 3
	LPRC	TPOR + TPWRT	TLPRC	1, 2, 3
	ECPLL	TPOR + TPWRT	TLOCK	1, 2, 4
	FRCPLL	TPOR + TPWRT	TFRC + TLOCK	1, 2, 3, 4
	XT, HS, SOSC	TPOR+ TPWRT	TOST	1, 2, 5
	XTPLL, HSPLL	TPOR + TPWRT	TOST + TLOCK	1, 2, 4, 5
BOR	EC	TPWRT	—	2
	FRC, FRCDIV	TPWRT	TFRC	2, 3
	LPRC	TPWRT	TLPRC	2, 3
	ECPLL	TPWRT	TLOCK	2, 4
	FRCPLL	TPWRT	TFRC + TLOCK	2, 3, 4
	XT, HS, SOSC	TPWRT	TOST	2, 5
	XTPLL, HSPLL	TPWRT	TFRC + TLOCK	2, 3, 4
All Others	Any Clock	—	—	None

Note 1: TPOR = Power-on Reset delay.

2: TPWRT = 64 ms nominal if the Power-up Timer is enabled; otherwise, it is zero.

3: TFRC and TLPRC = RC Oscillator start-up times.

4: TLOCK = PLL Lock time.

5: TOST = Oscillator Start-up Timer (OST). A 10-bit counter waits 1024 oscillator periods before releasing the oscillator clock to the system.

6: If Two-Speed Start-up is enabled, regardless of the Primary Oscillator selected, the device starts with FRC, and in such cases, FRC start-up time is valid.

Note: For detailed operating frequency and timing specifications, see **Section 27.0 "Electrical Characteristics"**.

8.0 INTERRUPT CONTROLLER

Note:	This data sheet summarizes the features of this group of PIC24F devices. It is not intended to be a comprehensive reference source. For more information on the Interrupt Controller, refer to the *"PIC24F Family Reference Manual"*, **"Interrupts"** (DS39707).

The PIC24F interrupt controller reduces the numerous peripheral interrupt request signals to a single interrupt request signal to the CPU. It has the following features:

- Up to Eight Processor Exceptions and Software Traps
- Seven User-Selectable Priority Levels
- Interrupt Vector Table (IVT) with up to 118 Vectors
- Unique Vector for Each Interrupt or Exception Source
- Fixed Priority within a Specified User Priority Level
- Alternate Interrupt Vector Table (AIVT) for Debug Support
- Fixed Interrupt Entry and Return Latencies

8.1 Interrupt Vector Table (IVT)

The IVT is shown in Figure 8-1. The IVT resides in the program memory, starting at location, 000004h. The IVT contains 126 vectors, consisting of eight non-maskable trap vectors, plus up to 118 sources of interrupt. In general, each interrupt source has its own vector. Each interrupt vector contains a 24-bit-wide address. The value programmed into each interrupt vector location is the starting address of the associated Interrupt Service Routine (ISR).

Interrupt vectors are prioritized in terms of their natural priority; this is linked to their position in the vector table. All other things being equal, lower addresses have a higher natural priority. For example, the interrupt associated with Vector 0 will take priority over interrupts at any other vector address.

PIC24FV16KM204 family devices implement non-maskable traps and unique interrupts; these are summarized in Table 8-1.

8.1.1 ALTERNATE INTERRUPT VECTOR TABLE (AIVT)

The Alternate Interrupt Vector Table (AIVT) is located after the IVT, as shown in Figure 8-1. Access to the AIVT is provided by the ALTIVT control bit (INTCON2<15>). If the ALTIVT bit is set, all interrupt and exception processes will use the alternate vectors instead of the default vectors. The alternate vectors are organized in the same manner as the default vectors.

The AIVT supports emulation and debugging efforts by providing a means to switch between an application and a support environment without requiring the interrupt vectors to be reprogrammed. This feature also enables switching between applications for evaluation of different software algorithms at run time. If the AIVT is not needed, the AIVT should be programmed with the same addresses used in the IVT.

8.2 Reset Sequence

A device Reset is not a true exception, because the interrupt controller is not involved in the Reset process. The PIC24F devices clear their registers in response to a Reset, which forces the Program Counter (PC) to zero. The microcontroller then begins program execution at location, 000000h. The user programs a GOTO instruction at the Reset address, which redirects the program execution to the appropriate start-up routine.

Note:	Any unimplemented or unused vector locations in the IVT and AIVT should be programmed with the address of a default interrupt handler routine that contains a RESET instruction.

8.3 Interrupt Control and Status Registers

The PIC24FV16KM204 family of devices implements a total of 33 registers for the interrupt controller:

- INTCON1
- INTCON2
- IFS0 through IFS6
- IEC0 through IEC6
- IPC0 through IPC7, IPC10, IPC12, IPC15, IPC16, IPC18 through IPC20 and IPC24
- INTTREG

Global Interrupt Enable (GIE) control functions are controlled from INTCON1 and INTCON2. INTCON1 contains the Interrupt Nesting Disable (NSTDIS) bit, as well as the control and status flags for the processor trap sources. The INTCON2 register controls the external interrupt request signal behavior and the use of the AIVT.

The IFSx registers maintain all of the interrupt request flags. Each source of interrupt has a status bit, which is set by the respective peripherals, or external signal, and is cleared via software.

The IECx registers maintain all of the interrupt enable bits. These control bits are used to individually enable interrupts from the peripherals or external signals.

The IPCx registers are used to set the Interrupt Priority Level (IPL) for each source of interrupt. Each user interrupt source can be assigned to one of eight priority levels.

The INTTREG register contains the associated interrupt vector number and the new CPU Interrupt Priority Level, which are latched into the Vector Number (VECNUM<6:0>) and the Interrupt Level (ILR<3:0>) bit fields in the INTTREG register. The new Interrupt Priority Level is the priority of the pending interrupt.

The interrupt sources are assigned to the IFSx, IECx and IPCx registers in the same sequence. For example, the INT0 (External Interrupt 0) is depicted as having a vector number and a natural order priority of 0. The INT0IF status bit is found in IFS0<0>, the INT0IE enable bit in IEC0<0> and the INT0IP<2:0> priority bits are in the first position of IPC0 (IPC0<2:0>).

Although they are not specifically part of the interrupt control hardware, two of the CPU Control registers contain bits that control interrupt functionality. The ALU STATUS Register (SR) contains the IPL<2:0> bits (SR<7:5>). These indicate the current CPU Interrupt Priority Level. The user may change the current CPU Interrupt Priority Level by writing to the IPLx bits.

The CORCON register contains the IPL3 bit, which together with IPL<2:0>, also indicates the current CPU Interrupt Priority Level. IPL3 is a read-only bit so that the trap events cannot be masked by the user's software.

All Interrupt registers are described in Register 8-1 through Register 8-35, in the following sections.

REGISTER 8-13: IEC1: INTERRUPT ENABLE CONTROL REGISTER 1

R/W-0	R/W-0	R/W-0	R/W-0	R/W-0	U-0	U-0	U-0

bit 3 **CNIE:** Input Change Notification Interrupt Enable bit
1 = Interrupt request is enabled
0 = Interrupt request is not enabled

bit 2 **CMIE:** Comparator Interrupt Enable bit
1 = Interrupt request is enabled
0 = Interrupt request is not enabled

bit 1 **BCL1IE:** MSSP1 I^2C™ Bus Collision Interrupt Enable bit
1 = Interrupt request is enabled
0 = Interrupt request is not enabled

bit 0 **SSP1IE:** MSSP1 SPI/I^2C Event Interrupt Enable bit
1 = Interrupt request is enabled
0 = Interrupt request is not enabled

10.2.2 IDLE MODE

Idle mode includes these features:

- The CPU will stop executing instructions.
- The WDT is automatically cleared.
- The system clock source remains active. By default, all peripheral modules continue to operate normally from the system clock source, but can also be selectively disabled (see **Section 10.6 "Selective Peripheral Module Control"**).
- If the WDT or FSCM is enabled, the LPRC will also remain active.

The device will wake from Idle mode on any of these events:

- Any interrupt that is individually enabled
- Any device Reset
- A WDT time-out

On wake-up from Idle, the clock is reapplied to the CPU and instruction execution begins immediately, starting with the instruction following the PWRSAV instruction or the first instruction in the ISR.

10.2.3 INTERRUPTS COINCIDENT WITH POWER SAVE INSTRUCTIONS

Any interrupt that coincides with the execution of a PWRSAV instruction will be held off until entry into Sleep or Idle mode has completed. The device will then wake-up from Sleep or Idle mode.

10.2.3.1 Power-on Resets (PORs)

VDD voltage is monitored to produce PORs. When a true POR occurs, the entire device is reset.

10.3 Ultra Low-Power Wake-up

The Ultra Low-Power Wake-up (ULPWU) on pin, RB0, allows a slow falling voltage to generate an interrupt without excess current consumption.

To use this feature:

1. Charge the capacitor on RB0 by configuring the RB0 pin to an output and setting it to '1'.
2. Stop charging the capacitor by configuring RB0 as an input.
3. Discharge the capacitor by setting the ULPEN and ULPSINK bits in the ULPWCON register.
4. Configure Sleep mode.
5. Enter Sleep mode.

When the voltage on RB0 drops below VIL, the device wakes up and executes the next instruction.

This feature provides a low-power technique for periodically waking up the device from Sleep mode.

The time-out is dependent on the discharge time of the RC circuit on RB0.

When the ULPWU module wakes the device from Sleep mode, the ULPWUIF bit (IFS5<0>) is set. Software can check this bit upon wake-up to determine the wake-up source.

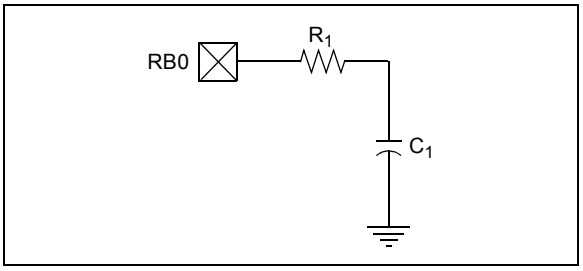
See Example 10-2 for initializing the ULPWU module.

EXAMPLE 10-2: ULTRA LOW-POWER WAKE-UP INITIALIZATION

```
//*****************************
// 1. Charge the capacitor on RB0
//*****************************
    TRISBbits.TRISB0 = 0;
    LATBbits.LATB0 = 1;
    for(i = 0; i < 10000; i++) Nop();
//*****************************
//2. Stop Charging the capacitor
//   on RB0
//*****************************
    TRISBbits.TRISB0 = 1;
//*****************************
//3. Enable ULPWU Interrupt
//*****************************
IFS5bits.ULPWUIF = 0;
IEC5bits.ULPWUIE = 1;
IPC21bits.ULPWUIP = 0x7;
//*****************************
//4. Enable the Ultra Low Power
//   Wakeup module and allow
//   capacitor discharge
//*****************************
    ULPWCONbits.ULPEN = 1;
    ULPWCONbit.ULPSINK = 1;
//*****************************
//5. Enter Sleep Mode
//*****************************
    Sleep();
//for sleep, execution will
//resume here
```

A series resistor, between RB0 and the external capacitor provides overcurrent protection for the AN2/ULPWU/RB0 pin and enables software calibration of the time-out (see Figure 10-1).

FIGURE 10-1: SERIES RESISTOR



A timer can be used to measure the charge time and discharge time of the capacitor. The charge time can then be adjusted to provide the desired delay in Sleep. This technique compensates for the affects of temperature, voltage and component accuracy. The peripheral can also be configured as a simple, programmable Low-Voltage Detect (LVD) or temperature sensor.

10.5 Doze Mode

Generally, changing clock speed and invoking one of the power-saving modes are the preferred strategies for reducing power consumption. There may be circumstances, however, where this is not practical. For example, it may be necessary for an application to maintain uninterrupted synchronous communication, even while it is doing nothing else. Reducing system clock speed may introduce communication errors, while using a power-saving mode may stop communications completely.

Doze mode is a simple and effective alternative method to reduce power consumption while the device is still executing code. In this mode, the system clock continues to operate from the same source and at the same speed. Peripheral modules continue to be clocked at the same speed, while the CPU clock speed is reduced. Synchronization between the two clock domains is maintained, allowing the peripherals to access the SFRs while the CPU executes code at a slower rate.

Doze mode is enabled by setting the DOZEN bit (CLKDIV<11>). The ratio between peripheral and core clock speed is determined by the DOZE<2:0> bits (CLKDIV<14:12>). There are eight possible configurations, from 1:1 to 1:128, with 1:1 being the default.

It is also possible to use Doze mode to selectively reduce power consumption in event driven applications. This allows clock-sensitive functions, such as synchronous communications, to continue without interruption. Meanwhile, the CPU Idles, waiting for something to invoke an interrupt routine. Enabling the automatic return to full-speed CPU operation on interrupts is enabled by setting the ROI bit (CLKDIV<15>). By default, interrupt events have no effect on Doze mode operation.

10.6 Selective Peripheral Module Control

Idle and Doze modes allow users to substantially reduce power consumption by slowing or stopping the CPU clock. Even so, peripheral modules still remain clocked, and thus, consume power. There may be cases where the application needs what these modes do not provide: the allocation of power resources to CPU processing with minimal power consumption from the peripherals.

PIC24F devices address this requirement by allowing peripheral modules to be selectively disabled, reducing or eliminating their power consumption. This can be done with two control bits:

- The Peripheral Enable bit, generically named, “XXXEN”, located in the module’s main control SFR.
- The Peripheral Module Disable (PMD) bit, generically named, “XXXMD”, located in one of the PMDx Control registers.

Both bits have similar functions in enabling or disabling its associated module. Setting the PMDx bits for a module, disables all clock sources to that module, reducing its power consumption to an absolute minimum. In this state, the control and status registers associated with the peripheral will also be disabled, so writes to those registers will have no effect, and read values will be invalid. Many peripheral modules have a corresponding PMDx bit.

In contrast, disabling a module by clearing its XXXEN bit, disables its functionality, but leaves its registers available to be read and written to. Power consumption is reduced, but not by as much as when the PMDx bits are used. Most peripheral modules have an enable bit; exceptions include capture, compare and RTCC.

To achieve more selective power savings, peripheral modules can also be selectively disabled when the device enters Idle mode. This is done through the control bit of the generic name format, “XXXIDL”. By default, all modules that can operate during Idle mode will do so. Using the disable on Idle feature disables the module while in Idle mode, allowing further reduction of power consumption during Idle mode, enhancing power savings for extremely critical power applications.

0 = Start condition is Idle
Slave Mode:
1 = Clock stretching is enabled for both slave transmit and slave receive (stretch is enabled)
0 = Clock stretching is disabled

Note 1: The value that will be transmitted when the user initiates an Acknowledge sequence at the end of a receive.

2: If the I^2C module is active, these bits may not be set (no spooling) and the SSPxBUF may not be written (or writes to the SSPxBUF are disabled).

NOTES:

15.2 Transmitting in 8-Bit Data Mode

1. Set up the UARTx:
   a) Write the appropriate values for data, parity and Stop bits.
   b) Write the appropriate baud rate value to the UxBRG register.
   c) Set up transmit and receive interrupt enable and priority bits.
2. Enable the UARTx.
3. Set the UTXEN bit (causes a transmit interrupt, two cycles after being set).
4. Write the data byte to the lower byte of the UxTXREG word. The value will be immediately transferred to the Transmit Shift Register (TSR) and the serial bit stream will start shifting out with the next rising edge of the baud clock.
5. Alternately, the data byte may be transferred while UTXEN = 0, and then, the user may set UTXEN. This will cause the serial bit stream to begin immediately, because the baud clock will start from a cleared state.
6. A transmit interrupt will be generated as per interrupt control bit, UTXISELx.

15.3 Transmitting in 9-Bit Data Mode

1. Set up the UARTx (as described in **Section 15.2 "Transmitting in 8-Bit Data Mode"**).
2. Enable the UARTx.
3. Set the UTXEN bit (causes a transmit interrupt, two cycles after being set).
4. Write UxTXREG as a 16-bit value only.
5. A word write to UxTXREG triggers the transfer of the 9-bit data to the TSR. The serial bit stream will start shifting out with the first rising edge of the baud clock.
6. A transmit interrupt will be generated as per the setting of control bit, UTXISELx.

15.4 Break and Sync Transmit Sequence

The following sequence will send a message frame header, made up of a Break, followed by an Auto-Baud Sync byte.

1. Configure the UARTx for the desired mode.
2. Set UTXEN and UTXBRK – this sets up the Break character.
3. Load the UxTXREG with a dummy character to initiate transmission (value is ignored).
4. Write '55h' to UxTXREG – loads the Sync character into the transmit FIFO.
5. After the Break has been sent, the UTXBRK bit is reset by hardware. The Sync character now transmits.

15.5 Receiving in 8-Bit or 9-Bit Data Mode

1. Set up the UARTx (as described in **Section 15.2 "Transmitting in 8-Bit Data Mode"**).
2. Enable the UARTx.
3. A receive interrupt will be generated when one or more data characters have been received, as per interrupt control bit, URXISELx.
4. Read the OERR bit to determine if an overrun error has occurred. The OERR bit must be reset in software.
5. Read UxRXREG.

The act of reading the UxRXREG character will move the next character to the top of the receive FIFO, including a new set of PERR and FERR values.

15.6 Operation of $\overline{\text{UxCTS}}$ and $\overline{\text{UxRTS}}$ Control Pins

UARTx Clear-To-Send ($\overline{\text{UxCTS}}$) and Request-To-Send ($\overline{\text{UxRTS}}$) are the two hardware controlled pins that are associated with the UARTx module. These two pins allow the UARTx to operate in Simplex and Flow Control modes. They are implemented to control the transmission and reception between the Data Terminal Equipment (DTE). The UEN<1:0> bits in the UxMODE register configure these pins.

15.7 Infrared Support

The UARTx module provides two types of infrared UARTx support: one is the IrDA clock output to support an external IrDA encoder and decoder device (legacy module support), and the other is the full implementation of the IrDA encoder and decoder.

As the IrDA modes require a 16x baud clock, they will only work when the BRGH bit (UxMODE<3>) is '0'.

15.7.1 EXTERNAL IrDA SUPPORT – IrDA CLOCK OUTPUT

To support external IrDA encoder and decoder devices, the UxBCLK pin (same as the $\overline{\text{UxRTS}}$ pin) can be configured to generate the 16x baud clock. When UEN<1:0> = 11, the UxBCLK pin will output the 16x baud clock if the UARTx module is enabled; it can be used to support the IrDA codec chip.

15.7.2 BUILT-IN IrDA ENCODER AND DECODER

The UARTx has full implementation of the IrDA encoder and decoder as part of the UARTx module. The built-in IrDA encoder and decoder functionality is enabled using the IREN bit (UxMODE<12>). When enabled (IREN = 1), the receive pin (UxRX) acts as the input from the infrared receiver. The transmit pin (UxTX) acts as the output to the infrared transmitter.

16.2.4 RTCC CONTROL REGISTERS

REGISTER 16-1: RCFGCAL: RTCC CALIBRATION AND CONFIGURATION REGISTER(1)

R/W-0	U-0	R/W-0	R-0, HSC	R-0, HSC	R/W-0	R/W-0	R/W-0
RTCEN(2)	—	RTCWREN	RTCSYNC	HALFSEC(3)	RTCOE	RTCPTR1	RTCPTR0
bit 15							bit 8

R/W-0	R/W-0	R/W-0	R/W-0	R/W-0	R/W-0	R/W-0	R/W-0
CAL7	CAL6	CAL5	CAL4	CAL3	CAL2	CAL1	CAL0
bit 7							bit 0

Legend:	HSC = Hardware Settable/Clearable bit		
R = Readable bit	W = Writable bit	U = Unimplemented bit, read as '0'	
-n = Value at POR	'1' = Bit is set	'0' = Bit is cleared	x = Bit is unknown

bit 15 **RTCEN:** RTCC Enable bit(2)
1 = RTCC module is enabled
0 = RTCC module is disabled

bit 14 **Unimplemented:** Read as '0'

bit 13 **RTCWREN:** RTCC Value Registers Write Enable bit
1 = RTCVALH and RTCVALL registers can be written to by the user
0 = RTCVALH and RTCVALL registers are locked out from being written to by the user

bit 12 **RTCSYNC:** RTCC Value Registers Read Synchronization bit
1 = RTCVALH, RTCVALL and ALCFGRPT registers can change while reading due to a rollover ripple resulting in an invalid data read. If the register is read twice and results in the same data, the data can be assumed to be valid.
0 = RTCVALH, RTCVALL or ALCFGRPT registers can be read without concern over a rollover ripple

bit 11 **HALFSEC:** Half Second Status bit(3)
1 = Second half period of a second
0 = First half period of a second

bit 10 **RTCOE:** RTCC Output Enable bit
1 = RTCC output is enabled
0 = RTCC output is disabled

bit 9-8 **RTCPTR<1:0>:** RTCC Value Register Window Pointer bits
Points to the corresponding RTCC Value registers when reading the RTCVALH and RTCVALL registers. The RTCPTR<1:0> value decrements on every read or write of RTCVALH until it reaches '00'.
RTCVAL<15:8>:
00 = MINUTES
01 = WEEKDAY
10 = MONTH
11 = Reserved
RTCVAL<7:0>:
00 = SECONDS
01 = HOURS
10 = DAY
11 = YEAR

Note 1: The RCFGCAL register is only affected by a POR.
2: A write to the RTCEN bit is only allowed when RTCWREN = 1.
3: This bit is read-only; it is cleared to '0' on a write to the lower half of the MINSEC register.

FIGURE 16-2: ALARM MASK SETTINGS

Alarm Mask Setting (AMASK<3:0>)	Day of the Week	Month	Day	Hours	Minutes	Seconds
0000 - Every half second 0001 - Every second						
0010 - Every 10 seconds						s
0011 - Every minute						s s
0100 - Every 10 minutes					m	s s
0101 - Every hour					m m	s s
0110 - Every day				h h	m m	s s
0111 - Every week	d			h h	m m	s s
1000 - Every month			d d	h h	m m	s s
1001 - Every year(1)		m m	d d	h h	m m	s s

Note 1: Annually, except when configured for February 29.

16.5 Power Control

The RTCC includes a power control feature that allows the device to periodically wake-up an external device, wait for the device to be stable before sampling wake-up events from that device and then shut down the external device. This can be done completely autonomously by the RTCC, without the need to wake from the current low-power mode (Sleep, Deep Sleep, etc.).

To enable this feature, the RTCC must be enabled (RTCEN = 1), the PWCEN register bit must be set and the RTCC pin must be driving the PWC control signal (RTCOE = 1 and RTCCLK<1:0> = 11).

The polarity of the PWC control signal may be chosen using the PWCPOL register bit. Active-low or active-high may be used with the appropriate external switch to turn on or off the power to one or more external devices. The active-low setting may also be used in conjunction with an open-drain setting on the RTCC pin. This setting is able to drive the GND pin(s) of the external device directly (with the appropriate external V_{DD} pull-up device), without the need for external switches. Finally, the CHIME bit should be set to enable the PWC periodicity.

REGISTER 17-3: CLCxSEL: CLCx INPUT MUX SELECT REGISTER

U-0	R/W-0	R/W-0	R/W-0	U-0	R/W-0	R/W-0	R/W-0
—	DS42	DS41	DS40	—	DS32	DS31	DS30
bit 15							bit 8

U-0	R/W-0	R/W-0	R/W-0	U-0	R/W-0	R/W-0	R/W-0
—	DS22	DS21	DS20	—	DS12	DS11	DS10
bit 7							bit 0

Legend:			
R = Readable bit	W = Writable bit	U = Unimplemented bit, read as '0'	
-n = Value at POR	'1' = Bit is set	'0' = Bit is cleared	x = Bit is unknown

bit 15 **Unimplemented:** Read as '0'

bit 14-12 **DS4<2:0>:** Data Selection MUX 4 Signal Selection bits
111 = MCCP3 Compare Event Flag (CCP3IF)

000 = CLCINB I/O pin
For CLC2:
011 = SPI2 SDIx
010 = Comparator 3 output
001 = CLC1 output
000 = CLCINB I/O pin

bit 11 **Unimplemented:** Read as '0'

bit 10-8 **DS3<2:0>:** Data Selection MUX 3 Signal Selection bits
111 = MCCP3 Compare Event Flag (CCP3IF)
110 = MCCP2 Compare Event Flag (CCP2IF)
101 = Digital logic low
For CLC1:
100 = UART1 RX
011 = SPI1 SDOx
010 = Comparator 2 output
001 = CLC1 output
000 = CLCINA I/O pin
For CLC2:
100 = UART2 RX
011 = SPI2 SDOx
010 = Comparator 2 output
001 = CLC2 output
000 = CLCINA I/O pin

bit 7 **Unimplemented:** Read as '0'

20.0 8-BIT DIGITAL-TO-ANALOG CONVERTER (DAC)

Note: This data sheet summarizes the features of this group of PIC24F devices. It is not intended to be a comprehensive reference source. For more information, refer to the *"PIC24F Family Reference Manual"*. Device-specific information in this data sheet supersedes the information in the *"PIC24F Family Reference Manual"*.

PIC24FV16KM204 family devices include two 8-bit Digital-to-Analog Converters (DACs) for generating analog outputs from digital data. A simplified block diagram for a single DAC is shown in Figure 20-1. Both of the DACs are identical.

The DAC generates an analog output voltage based on the digital input code, according to the formula:

$$V_{DAC} = \frac{V_{DACREF} \times DACxDAT}{256}$$

where V_{DAC} is the analog output voltage and V_{DACREF} is the reference voltage selected by DACREF<1:0>.

Each DAC includes these features:

- Precision 8-bit resistor ladder for high accuracy
- Fast settling time, supporting 1 Msps effective sampling rates
- Buffered output voltage
- Three user-selectable voltage reference options
- Multiple conversion Trigger options, plus a manual convert-on-write option
- Left and right justified input data options
- User-selectable Sleep and Idle mode operation

When using the DAC, it is recommended to set the ANSx and TRISx bits for the DACx output pin to configure it as an analog output. See **Section 11.2 "Configuring Analog Port Pins"** for more information.
