

Welcome to [E-XFL.COM](#)

### What is "[Embedded - Microcontrollers](#)"?

"[Embedded - Microcontrollers](#)" refer to small, integrated circuits designed to perform specific tasks within larger systems. These microcontrollers are essentially compact computers on a single chip, containing a processor core, memory, and programmable input/output peripherals. They are called "embedded" because they are embedded within electronic devices to control various functions, rather than serving as standalone computers. Microcontrollers are crucial in modern electronics, providing the intelligence and control needed for a wide range of applications.

### Applications of "[Embedded - Microcontrollers](#)"

#### Details

Product Status	Obsolete
Core Processor	ST7
Core Size	8-Bit
Speed	8MHz
Connectivity	CANbus, LINbusSCI, SPI
Peripherals	LVD, POR, PWM, WDT
Number of I/O	48
Program Memory Size	60KB (60K x 8)
Program Memory Type	FLASH
EEPROM Size	-
RAM Size	2K x 8
Voltage - Supply (Vcc/Vdd)	3.8V ~ 5.5V
Data Converters	A/D 16x10b
Oscillator Type	External
Operating Temperature	-40°C ~ 85°C (TA)
Mounting Type	Surface Mount
Package / Case	64-LQFP
Supplier Device Package	-
Purchase URL	<a href="https://www.e-xfl.com/product-detail/stmicroelectronics/st72f561r9ta">https://www.e-xfl.com/product-detail/stmicroelectronics/st72f561r9ta</a>

### 3 REGISTER AND MEMORY MAP

As shown in Figure 5, the MCU is capable of addressing 64 Kbytes of memories and I/O registers. The available memory locations consist of 128 bytes of register locations, up to 2 Kbytes of RAM and up to 60 Kbytes of user program memory.

The RAM space includes up to 256 bytes for the stack from 0100h to 01FFh. The highest address bytes contain the user reset and interrupt vectors.

**IMPORTANT:** Memory locations marked as “Reserved” must never be accessed. Accessing a reserved area can have unpredictable effects on the device.

**Figure 5. Memory Map**

## POWER SAVING MODES (Cont'd)

## 8.3 WAIT MODE

WAIT mode places the MCU in a low power consumption mode by stopping the CPU.

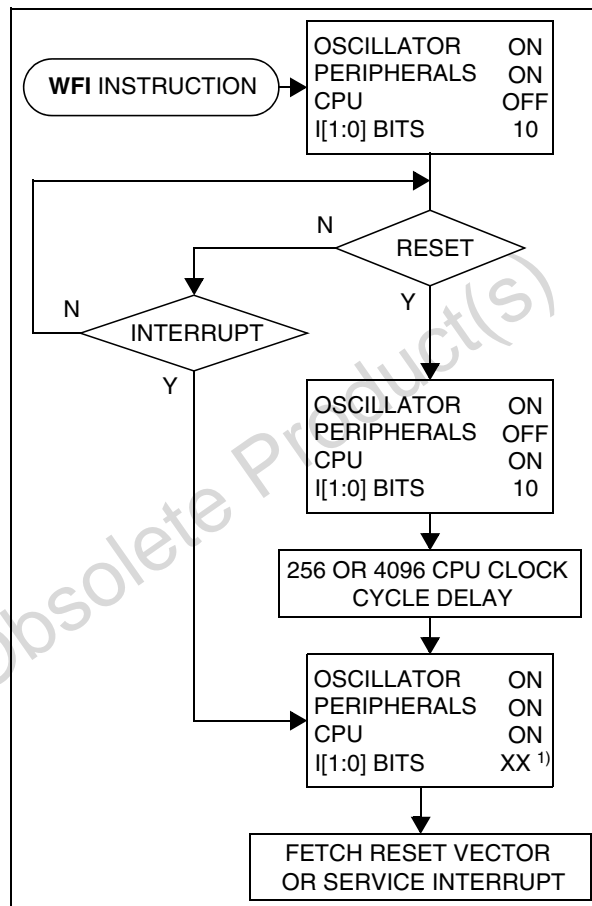

This power saving mode is selected by calling the 'WFI' instruction.

All peripherals remain active. During WAIT mode, the I[1:0] bits of the CC register are forced to '10', to enable all interrupts. All other registers and memory remain unchanged. The MCU remains in WAIT mode until an interrupt or RESET occurs, whereupon the Program Counter branches to the starting address of the interrupt or Reset service routine.

The MCU will remain in WAIT mode until a Reset or an Interrupt occurs, causing it to wake up.

Refer to [Figure 24](#)

Figure 24. WAIT Mode Flow-chart

**Note:**

1. Before servicing an interrupt, the CC register is pushed on the stack. The I[1:0] bits of the CC register are set to the current software priority level of the interrupt routine and recovered when the CC register is popped.

**WINDOW WATCHDOG (Cont'd)**

The application program must write in the WDGCR register at regular intervals during normal operation to prevent an MCU reset. This operation must occur only when the counter value is lower than the window register value. The value to be stored in the WDGCR register must be between FFh and C0h (see [Figure 2](#)):

- Enabling the watchdog:  
When Software Watchdog is selected (by option byte), the watchdog is disabled after a reset. It is enabled by setting the WDGA bit in the WDGCR register, then it cannot be disabled again except by a reset.

When Hardware Watchdog is selected (by option byte), the watchdog is always active and the WDGA bit is not used.

- Controlling the downcounter:  
This downcounter is free-running: It counts down even if the watchdog is disabled. When the watchdog is enabled, the T6 bit must be set to prevent generating an immediate reset. The T[5:0] bits contain the number of increments which represents the time delay before the watchdog produces a reset (see [Figure 2. Approximate Timeout Duration](#)). The timing varies

between a minimum and a maximum value due to the unknown status of the prescaler when writing to the WDGCR register (see [Figure 3](#)).

The window register (WDGWR) contains the high limit of the window: To prevent a reset, the downcounter must be reloaded when its value is lower than the window register value and greater than 3Fh. [Figure 4](#) describes the window watchdog process.

**Note:** The T6 bit can be used to generate a software reset (the WDGA bit is set and the T6 bit is cleared).

- Watchdog Reset on Halt option  
If the watchdog is activated and the watchdog reset on halt option is selected, then the HALT instruction will generate a Reset.

**10.1.4 Using Halt Mode with the WDG**

If Halt mode with Watchdog is enabled by option byte (no watchdog reset on HALT instruction), it is recommended before executing the HALT instruction to refresh the WDG counter, to avoid an unexpected WDG reset immediately after waking up the microcontroller.

## WINDOW WATCHDOG (Cont'd)

Figure 36. Exact Timeout Duration ( $t_{\min}$  and  $t_{\max}$ )**WHERE:**

$$t_{\min 0} = (\text{LSB} + 128) \times 64 \times t_{\text{OSC2}}$$

$$t_{\max 0} = 16384 \times t_{\text{OSC2}}$$

$$t_{\text{OSC2}} = 125\text{ns if } f_{\text{OSC2}} = 8 \text{ MHz}$$

CNT = Value of T[5:0] bits in the WDGCR register (6 bits)

MSB and LSB are values from the table below depending on the timebase selected by the TB[1:0] bits in the MCCR register

TB1 Bit (MCCR Reg.)	TB0 Bit (MCCR Reg.)	Selected MCCR Timebase	MSB	LSB
0	0	2ms	4	59
0	1	4ms	8	53
1	0	10ms	20	35
1	1	25ms	49	54

**To calculate the minimum Watchdog Timeout ( $t_{\min}$ ):**

$$\text{IF } \text{CNT} < \left\lceil \frac{\text{MSB}}{4} \right\rceil \quad \text{THEN } t_{\min} = t_{\min 0} + 16384 \times \text{CNT} \times t_{\text{osc2}}$$

$$\text{ELSE } t_{\min} = t_{\min 0} + \left[ 16384 \times \left( \text{CNT} - \left\lceil \frac{4\text{CNT}}{\text{MSB}} \right\rceil \right) + (192 + \text{LSB}) \times 64 \times \left\lceil \frac{4\text{CNT}}{\text{MSB}} \right\rceil \right] \times t_{\text{osc2}}$$

**To calculate the maximum Watchdog Timeout ( $t_{\max}$ ):**

$$\text{IF } \text{CNT} \leq \left\lceil \frac{\text{MSB}}{4} \right\rceil \quad \text{THEN } t_{\max} = t_{\max 0} + 16384 \times \text{CNT} \times t_{\text{osc2}}$$

$$\text{ELSE } t_{\max} = t_{\max 0} + \left[ 16384 \times \left( \text{CNT} - \left\lceil \frac{4\text{CNT}}{\text{MSB}} \right\rceil \right) + (192 + \text{LSB}) \times 64 \times \left\lceil \frac{4\text{CNT}}{\text{MSB}} \right\rceil \right] \times t_{\text{osc2}}$$

**Note:** In the above formulae, division results must be rounded down to the next integer value.

**Example:**

With 2ms timeout selected in MCCR register

Value of T[5:0] Bits in WDGCR Register (Hex.)	Min. Watchdog Timeout (ms) $t_{\min}$	Max. Watchdog Timeout (ms) $t_{\max}$
00	1.496	2.048
3F	128	128.552

## WINDOW WATCHDOG (Cont'd)

Figure 37. Window Watchdog Timing Diagram

## 10.1.6 Low Power Modes

Mode	Description		
SLOW	No effect on Watchdog: The downcounter continues to decrement at normal speed.		
WAIT	No effect on Watchdog: The downcounter continues to decrement.		
	OIE bit in MCCR register	WDGHALT bit in Option Byte	
HALT	0	0	No Watchdog reset is generated. The MCU enters Halt mode. The Watchdog counter is decremented once and then stops counting and is no longer able to generate a watchdog reset until the MCU receives an external interrupt or a reset.  If an interrupt is received (refer to interrupt table mapping to see interrupts which can occur in halt mode), the Watchdog restarts counting after 256 or 4096 CPU clocks. If a reset is generated, the Watchdog is disabled (reset state) unless Hardware Watchdog is selected by option byte. For application recommendations see <a href="#">Section 0.1.8</a> below.
	0	1	A reset is generated instead of entering halt mode.
ACTIVE HALT	1	x	No reset is generated. The MCU enters Active Halt mode. The Watchdog counter is not decremented. It stop counting. When the MCU receives an oscillator interrupt or external interrupt, the Watchdog restarts counting immediately. When the MCU receives a reset the Watchdog restarts counting after 256 or 4096 CPU clocks.

## 10.1.7 Hardware Watchdog Option

If Hardware Watchdog is selected by option byte, the watchdog is always active and the WDGA bit in the WDGC is not used. Refer to the Option Byte description.

## 10.1.8 Using Halt Mode with the WDG (WDGHALT option)

The following recommendation applies if Halt mode is used when the watchdog is enabled.

- Before executing the HALT instruction, refresh the WDG counter, to avoid an unexpected WDG reset immediately after waking up the microcontroller.

**WINDOW WATCHDOG (Cont'd)****10.1.9 Interrupts**

None.

**10.1.10 Register Description****CONTROL REGISTER (WDGCR)**

Read/Write

Reset Value: 0111 1111 (7Fh)

7							0
WDGA	T6	T5	T4	T3	T2	T1	T0

Bit 7 = **WDGA** Activation bit.

This bit is set by software and only cleared by hardware after a reset. When WDGA = 1, the watchdog can generate a reset.

0: Watchdog disabled

1: Watchdog enabled

**Note:** This bit is not used if the hardware watchdog option is enabled by option byte.

Bits 6:0 = **T[6:0]** 7-bit counter (MSB to LSB).

These bits contain the value of the watchdog counter. It is decremented every 16384  $f_{OSC2}$  cycles (approx.). A reset is produced when it rolls over from 40h to 3Fh (T6 becomes cleared).

**WINDOW REGISTER (WDGWR)**

Read/Write

Reset Value: 0111 1111 (7Fh)

7							0
-	W6	W5	W4	W3	W2	W1	W0

Bit 7 = Reserved

Bits 6:0 = **W[6:0]** 7-bit window value

These bits contain the window value to be compared to the downcounter.

**Figure 38. Watchdog Timer Register Map and Reset Values**

Address (Hex.)	Register Label	7	6	5	4	3	2	1	0
2F	<b>WDGCR</b>	WDGA	T6	T5	T4	T3	T2	T1	T0
	Reset Value	0	1	1	1	1	1	1	1
30	<b>WDGWR</b>	-	W6	W5	W4	W3	W2	W1	W0
	Reset Value	0	1	1	1	1	1	1	1

## MAIN CLOCK CONTROLLER WITH REAL TIME CLOCK (Cont'd)

## 10.2.4 Low Power Modes

Mode	Description
WAIT	No effect on MCC/RTC peripheral. MCC/RTC interrupt cause the device to exit from WAIT mode.
ACTIVE HALT	No effect on MCC/RTC counter (OIE bit is set), the registers are frozen. MCC/RTC interrupt cause the device to exit from ACTIVE HALT mode.
HALT and AWUF HALT	MCC/RTC counter and registers are frozen. MCC/RTC operation resumes when the MCU is woken up by an interrupt with "exit from HALT" capability.

## 10.2.5 Interrupts

The MCC/RTC interrupt event generates an interrupt if the OIE bit of the MCCR register is set and the interrupt mask in the CC register is not active (RIM instruction).

Interrupt Event	Event Flag	Enable Control Bit	Exit from Wait	Exit from Halt
Time base overflow event	OIF	OIE	Yes	No <sup>1)</sup>

**Note:**

The MCC/RTC interrupt wakes up the MCU from ACTIVE HALT mode, not from HALT or AWUF HALT mode.

## 10.2.6 Register Description

## MCC CONTROL/STATUS REGISTER (MCCR)

Read/Write

Reset Value: 0000 0000 (00h)

7	0						
MCO	CP1	CP0	SMS	TB1	TB0	OIE	OIF

Bit 7 = **MCO** Main clock out selection

This bit enables the MCO alternate function on the corresponding I/O port. It is set and cleared by software.

0: MCO alternate function disabled (I/O pin free for general-purpose I/O)

1: MCO alternate function enabled ( $f_{OSC2}$  on I/O port)

Bits 6:5 = **CP[1:0]** CPU clock prescaler

These bits select the CPU clock prescaler which is applied in the different slow modes. Their action is conditioned by the setting of the SMS bit. These two bits are set and cleared by software

$f_{CPU}$ in SLOW mode	CP1	CP0
$f_{OSC2} / 2$	0	0
$f_{OSC2} / 4$	0	1
$f_{OSC2} / 8$	1	0
$f_{OSC2} / 16$	1	1

Bit 4 = **SMS** Slow mode select

This bit is set and cleared by software.

0: Normal mode.  $f_{CPU} = f_{OSC2}$

1: Slow mode.  $f_{CPU}$  is given by CP1, CP0

See [Section 8.2 "SLOW MODE"](#) and [Section 10.2 "MAIN CLOCK CONTROLLER WITH REAL TIME CLOCK MCC/RTC"](#) for more details.

Bits 3:2 = **TB[1:0]** Time base control

These bits select the programmable divider time base. They are set and cleared by software.

Counter Prescaler	Time Base		TB1	TB0
	$f_{OSC2} = 4 \text{ MHz}$	$f_{OSC2} = 8 \text{ MHz}$		
16000	4ms	2ms	0	0
32000	8ms	4ms	0	1
80000	20ms	10ms	1	0
200000	50ms	25ms	1	1

A modification of the time base is taken into account at the end of the current period (previously set) to avoid an unwanted time shift. This allows to use this time base as a real time clock.

Bit 1 = **OIE** Oscillator interrupt enable

This bit set and cleared by software.

0: Oscillator interrupt disabled

1: Oscillator interrupt enabled

This interrupt can be used to exit from ACTIVE HALT mode.

When this bit is set, calling the ST7 software HALT instruction enters the ACTIVE HALT power saving mode.

**ON-CHIP PERIPHERALS (Cont'd)****INPUT CAPTURE CONTROL / STATUS REGISTER (ARTICCSR)**

Read/Write

Reset Value: 0000 0000 (00h)

7							0
0	0	CS2	CS1	CIE2	CIE1	CF2	CF1

Bit 7:6 = Reserved, always read as 0.

**Bit 5:4 = CS[2:1] Capture Sensitivity**

These bits are set and cleared by software. They determine the trigger event polarity on the corresponding input capture channel.

0: Falling edge triggers capture on channel x.

1: Rising edge triggers capture on channel x.

**Bit 3:2 = CIE[2:1] Capture Interrupt Enable**

These bits are set and cleared by software. They enable or disable the Input capture channel interrupts independently.

0: Input capture channel x interrupt disabled.

1: Input capture channel x interrupt enabled.

**Bit 1:0 = CF[2:1] Capture Flag**

These bits are set by hardware and cleared by software reading the corresponding ARTICRx register. Each CFx bit indicates that an input capture x has occurred.

0: No input capture on channel x.

1: An input capture has occurred on channel x.

**INPUT CAPTURE REGISTERS (ARTICRx)**

Read only

Reset Value: 0000 0000 (00h)

7							0
IC7	IC6	IC5	IC4	IC3	IC2	IC1	IC0

**Bit 7:0 = IC[7:0] Input Capture Data**

These read only bits are set and cleared by hardware. An ARTICRx register contains the 8-bit auto-reload counter value transferred by the input capture channel x event.

**16-BIT TIMER** (Cont'd)**10.4.7 Register Description**

Each Timer is associated with three control and status registers, and with six pairs of data registers (16-bit values) relating to the two input captures, the two output compares, the counter and the alternate counter.

**CONTROL REGISTER 1 (CR1)**

Read/Write

Reset Value: 0000 0000 (00h)

7							0
ICIE	OCIE	TOIE	FOLV2	FOLV1	OLVL2	IEDG1	OLVL1

Bit 7 = **ICIE** *Input Capture Interrupt Enable*.

0: Interrupt is inhibited.

1: A timer interrupt is generated whenever the ICF1 or ICF2 bit of the SR register is set.

Bit 6 = **OCIE** *Output Compare Interrupt Enable*.

0: Interrupt is inhibited.

1: A timer interrupt is generated whenever the OCF1 or OCF2 bit of the SR register is set.

Bit 5 = **TOIE** *Timer Overflow Interrupt Enable*.

0: Interrupt is inhibited.

1: A timer interrupt is enabled whenever the TOF bit of the SR register is set.

Bit 4 = **FOLV2** *Forced Output Compare 2*.

This bit is set and cleared by software.

0: No effect on the OCMP2 pin.

1: Forces the OLVL2 bit to be copied to the OCMP2 pin, if the OC2E bit is set and even if there is no successful comparison.

Bit 3 = **FOLV1** *Forced Output Compare 1*.

This bit is set and cleared by software.

0: No effect on the OCMP1 pin.

1: Forces OLVL1 to be copied to the OCMP1 pin, if the OC1E bit is set and even if there is no successful comparison.

Bit 2 = **OLVL2** *Output Level 2*.

This bit is copied to the OCMP2 pin whenever a successful comparison occurs with the OC2R register and OCxE is set in the CR2 register. This value is copied to the OCMP1 pin in One Pulse mode and Pulse Width Modulation mode.

Bit 1 = **IEDG1** *Input Edge 1*.

This bit determines which type of level transition on the ICAP1 pin will trigger the capture.

0: A falling edge triggers the capture.

1: A rising edge triggers the capture.

Bit 0 = **OLVL1** *Output Level 1*.

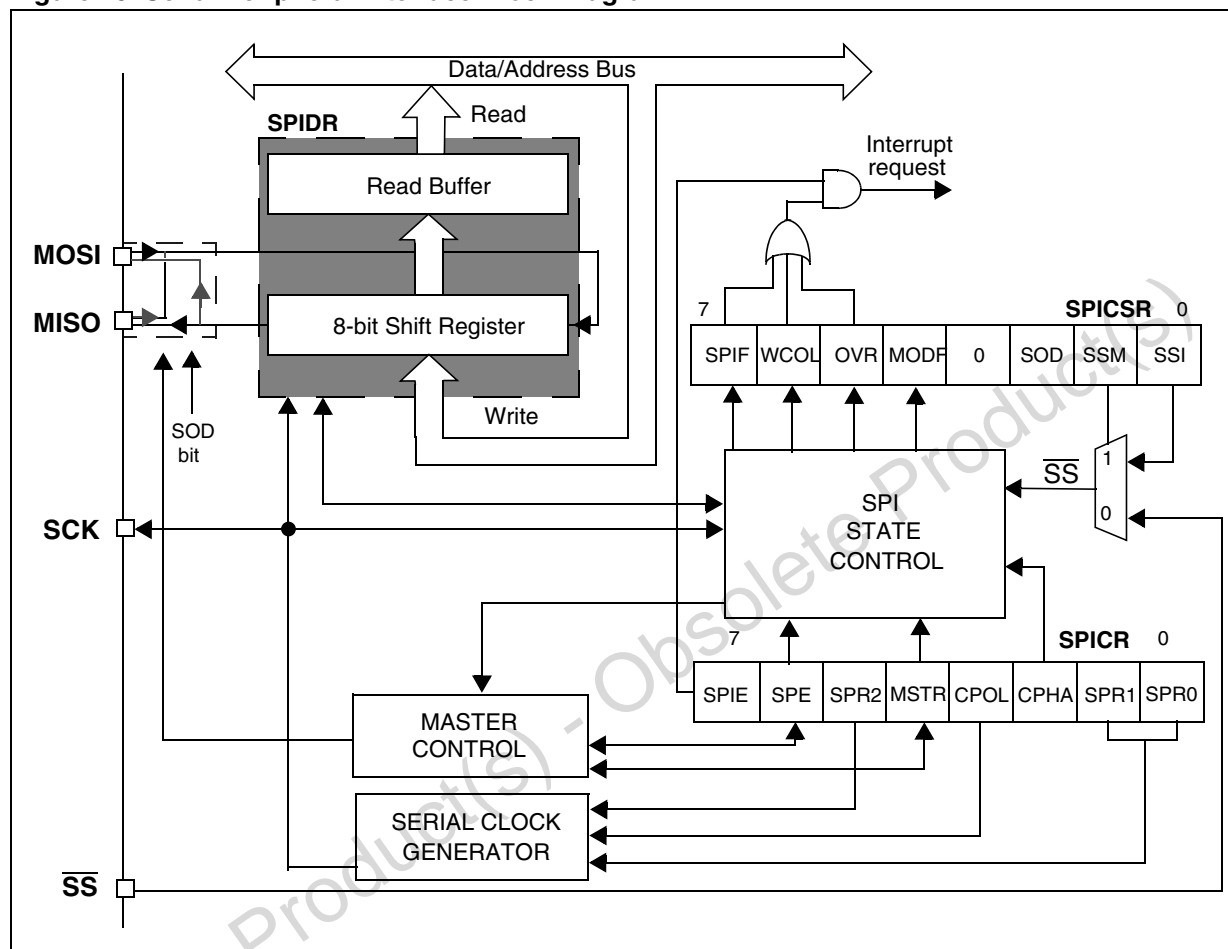

The OLVL1 bit is copied to the OCMP1 pin whenever a successful comparison occurs with the OC1R register and the OC1E bit is set in the CR2 register.

**16-BIT TIMER** (Cont'd)**Table 19. 16-Bit Timer Register Map**

Address (Hex.)	Register Name	7	6	5	4	3	2	1	0

## SERIAL PERIPHERAL INTERFACE (SPI) (cont'd)

Figure 70. Serial Peripheral Interface Block Diagram

**SERIAL PERIPHERAL INTERFACE (cont'd)****10.6.5 Error Flags****10.6.5.1 Master Mode Fault (MODF)**

Master mode fault occurs when the master device's  $\overline{SS}$  pin is pulled low.

When a Master mode fault occurs:

- The MODF bit is set and an SPI interrupt request is generated if the SPIE bit is set.
- The SPE bit is reset. This blocks all output from the device and disables the SPI peripheral.
- The MSTR bit is reset, thus forcing the device into slave mode.

Clearing the MODF bit is done through a software sequence:

1. A read access to the SPICSR register while the MODF bit is set.
2. A write to the SPICR register.

**Notes:** To avoid any conflicts in an application with multiple slaves, the  $\overline{SS}$  pin must be pulled high during the MODF bit clearing sequence. The SPE and MSTR bits may be restored to their original state during or after this clearing sequence.

Hardware does not allow the user to set the SPE and MSTR bits while the MODF bit is set except in the MODF bit clearing sequence.

In a slave device, the MODF bit can not be set, but in a multimaster configuration the device can be in slave mode with the MODF bit set.

The MODF bit indicates that there might have been a multimaster conflict and allows software to handle this using an interrupt routine and either perform a reset or return to an application default state.

**10.6.5.2 Overrun Condition (OVR)**

An overrun condition occurs when the master device has sent a data byte and the slave device has not cleared the SPIF bit issued from the previously transmitted byte.

When an Overrun occurs:

- The OVR bit is set and an interrupt request is generated if the SPIE bit is set.

In this case, the receiver buffer contains the byte sent after the SPIF bit was last cleared. A read to the SPIDR register returns this byte. All other bytes are lost.

The OVR bit is cleared by reading the SPICSR register.

**10.6.5.3 Write Collision Error (WCOL)**

A write collision occurs when the software tries to write to the SPIDR register while a data transfer is taking place with an external device. When this happens, the transfer continues uninterrupted and the software write will be unsuccessful.

Write collisions can occur both in master and slave mode. See also [Section 10.6.3.2 "Slave Select Management"](#).

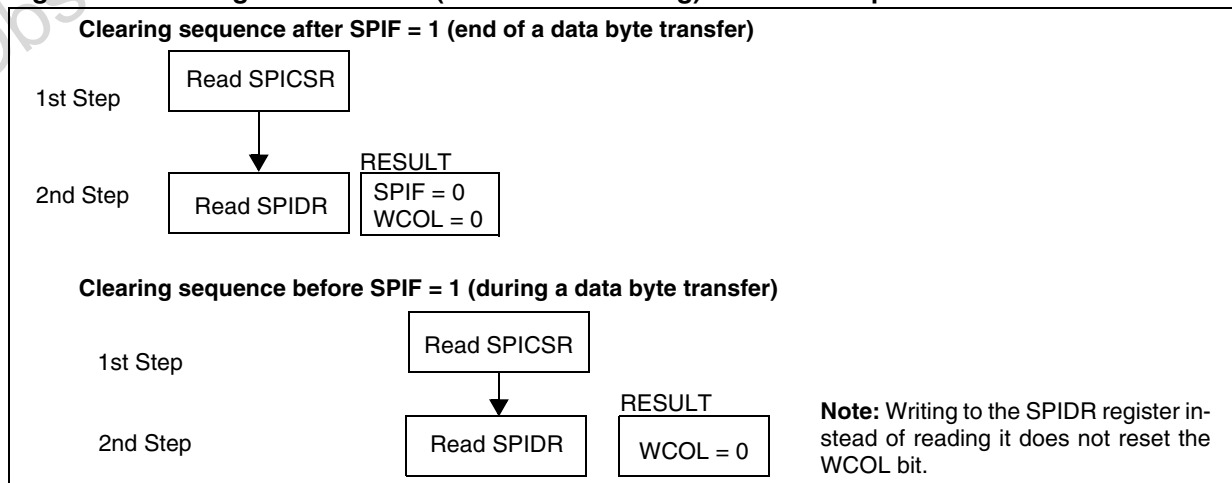

**Note:** A "read collision" will never occur since the received data byte is placed in a buffer in which access is always synchronous with the CPU operation.

The WCOL bit in the SPICSR register is set if a write collision occurs.

No SPI interrupt is generated when the WCOL bit is set (the WCOL bit is a status flag only).

Clearing the WCOL bit is done through a software sequence (see [Figure 75](#)).

**Figure 75. Clearing the WCOL Bit (Write Collision Flag) Software Sequence**

**LINSPI™ SERIAL COMMUNICATION INTERFACE (LIN Mode) (cont'd)**

If LHE bit is set due to this error during Fields other than LIN Synch Field or if LASE bit is reset then the current received Header is discarded and the SCI searches for a new Break Field.

**Note on LIN Header Time-out Limit**

According to the LIN specification, the maximum length of a LIN Header which does not cause a timeout is equal to  $1.4 * (34 + 1) = 49 T_{\text{BIT\_MASTER}}$ .

$T_{\text{BIT\_MASTER}}$  refers to the master baud rate.

When checking this timeout, the slave node is desynchronized for the reception of the LIN Break and Synch fields. Consequently, a margin must be allowed, taking into account the worst case: This occurs when the LIN identifier lasts exactly  $10 T_{\text{BIT\_MASTER}}$  periods. In this case, the LIN Break and Synch fields last  $49 - 10 = 39 T_{\text{BIT\_MASTER}}$  periods.

Assuming the slave measures these first 39 bits with a desynchronized clock of 15.5%. This leads to a maximum allowed Header Length of:

$$39 \times (1/0.845) T_{\text{BIT\_MASTER}} + 10 T_{\text{BIT\_MASTER}} = 56.15 T_{\text{BIT\_SLAVE}}$$

A margin is provided so that the time-out occurs when the header length is greater than  $57 T_{\text{BIT\_SLAVE}}$  periods. If it is less than or equal to  $57 T_{\text{BIT\_SLAVE}}$  periods, then no timeout occurs.

**LIN Header Length**

Even if no timeout occurs on the LIN Header, it is possible to have access to the effective LIN header Length ( $T_{\text{HEADER}}$ ) through the LHL register. This allows monitoring at software level the  $T_{\text{FRAME\_MAX}}$  condition given by the LIN protocol.

This feature is only available when LHDM bit = 1 or when LASE bit = 1.

**Mute Mode and Errors**

In mute mode when LHDM bit = 1, if an LHE error occurs during the analysis of the LIN Synch Field or if a LIN Header Time-out occurs then the LHE bit is set but it does not wake up from mute mode. In this case, the current header analysis is discarded. If needed, the software has to reset LSF bit. Then the SCI searches for a new LIN header.

In mute mode, if a framing error occurs on a data (which is not a break), it is discarded and the FE bit is not set.

When LHDM bit = 1, any LIN header which respects the following conditions causes a wake-up from mute mode:

- A valid LIN Break Field (at least 11 dominant bits followed by a recessive bit)
- A valid LIN Synch Field (without deviation error)
- A LIN Identifier Field without framing error. Note that a LIN parity error on the LIN Identifier Field does not prevent wake-up from mute mode.
- No LIN Header Time-out should occur during Header reception.

**Figure 83. LIN Synch Field Measurement**

**LINSPI™ SERIAL COMMUNICATION INTERFACE (LIN Mode) (cont'd)**

SCICR2 register is set, the LHDM bit selects the Wake-Up method (replacing the WAKE bit).

0: LIN Synch Break Detection Method

1: LIN Identifier Field Detection Method

**Bit 2 = LHIE LIN Header Interrupt Enable**

This bit is set and cleared by software. It is only usable in LIN Slave mode.

0: LIN Header Interrupt is inhibited.

1: An SCI interrupt is generated whenever LHDF = 1.

**Bit 1 = LHDF LIN Header Detection Flag**

This bit is set by hardware when a LIN Header is detected and cleared by a software sequence (an access to the SCISR register followed by a read of the SCICR3 register). It is only usable in LIN Slave mode.

0: No LIN Header detected.

1: LIN Header detected.

**Notes:** The header detection method depends on the LHDM bit:

- If LHDM = 0, a header is detected as a LIN Synch Break.
- If LHDM = 1, a header is detected as a LIN Identifier, meaning that a LIN Synch Break Field + a LIN Synch Field + a LIN Identifier Field have been consecutively received.

**Bit 0 = LSF LIN Synch Field State**

This bit indicates that the LIN Synch Field is being analyzed. It is only used in LIN Slave mode. In Auto Synchronization Mode (LASE bit = 1), when the SCI is in the LIN Synch Field State it waits or counts the falling edges on the RDI line.

It is set by hardware as soon as a LIN Synch Break is detected and cleared by hardware when the LIN Synch Field analysis is finished (see [Figure 11](#)). This bit can also be cleared by software to exit LIN Synch State and return to idle mode.

0: The current character is not the LIN Synch Field

1: LIN Synch Field State (LIN Synch Field under-going analysis)

**Figure 87. LSF Bit Set and Clear****LIN DIVIDER REGISTERS**

LDIV is coded using the two registers LPR and LPFR. In LIN Slave mode, the LPR register is accessible at the address of the SCIBRR register and the LPFR register is accessible at the address of the SCIETPR register.

**LIN PRESCALER REGISTER (LPR)**

**Read/Write**

Reset Value: 0000 0000 (00h)

7							0
LPR7	LPR6	LPR5	LPR4	LPR3	LPR2	LPR1	LPR0

**LPR[7:0] LIN Prescaler (mantissa of LDIV)**

These 8 bits define the value of the mantissa of the LIN Divider (LDIV):

LPR[7:0]	Rounded Mantissa (LDIV)
00h	SCI clock disabled
01h	1
...	...
FEh	254
FFh	255

**Caution:** LPR and LPFR registers have different meanings when reading or writing to them. Consequently bit manipulation instructions (BRES or BSET) should never be used to modify the LPR[7:0] bits, or the LPFR[3:0] bits.

## LINSCI™ SERIAL COMMUNICATION INTERFACE (LIN Master Only) (Cont'd)

### 10.8.4.4 Conventional Baud Rate Generation

The baud rates for the receiver and transmitter (Rx and Tx) are set independently and calculated as follows

:

$$Tx = \frac{f_{CPU}}{(16 \cdot PR) \cdot TR} \quad Rx = \frac{f_{CPU}}{(16 \cdot PR) \cdot RR}$$

with:

PR = 1, 3, 4 or 13 (see SCP[1:0] bits)

TR = 1, 2, 4, 8, 16, 32, 64, 128

(see SCT[2:0] bits)

RR = 1, 2, 4, 8, 16, 32, 64, 128

(see SCR[2:0] bits)

All these bits are in the SCIBRR register.

**Example:** If  $f_{CPU}$  is 8 MHz (normal mode) and if PR = 13 and TR = RR = 1, the transmit and receive baud rates are 38400 baud.

**Note:** The baud rate registers MUST NOT be changed while the transmitter or the receiver is enabled.

### 10.8.4.5 Extended Baud Rate Generation

The extended prescaler option gives a very fine tuning on the baud rate, using a 255 value prescaler, whereas the conventional Baud Rate Generator retains industry standard software compatibility.

The extended baud rate generator block diagram is described in the [Figure 90](#).

The output clock rate sent to the transmitter or to the receiver is the output from the 16 divider divided by a factor ranging from 1 to 255 set in the SCIERPR or the SCIETPR register.

**Note:** The extended prescaler is activated by setting the SCIETPR or SCIERPR register to a value

other than zero. The baud rates are calculated as follows:

$$Tx = \frac{f_{CPU}}{16 \cdot ETPR \cdot (PR \cdot TR)} \quad Rx = \frac{f_{CPU}}{16 \cdot ERPR \cdot (PR \cdot RR)}$$

with:

ETPR = 1, ..., 255 (see SCIETPR register)

ERPR = 1, ..., 255 (see SCIERPR register)

### 10.8.4.6 Receiver Muting and Wake-up Feature

In multiprocessor configurations it is often desirable that only the intended message recipient should actively receive the full message contents, thus reducing redundant SCI service overhead for all non addressed receivers.

The non addressed devices may be placed in sleep mode by means of the muting function.

Setting the RWU bit by software puts the SCI in sleep mode:

All the reception status bits cannot be set.

All the receive interrupts are inhibited.

A muted receiver may be awakened by one of the following two ways:

- by Idle Line detection if the WAKE bit is reset,
- by Address Mark detection if the WAKE bit is set.

Receiver wakes-up by Idle Line detection when the Receive line has recognized an Idle Frame. Then the RWU bit is reset by hardware but the IDLE bit is not set.

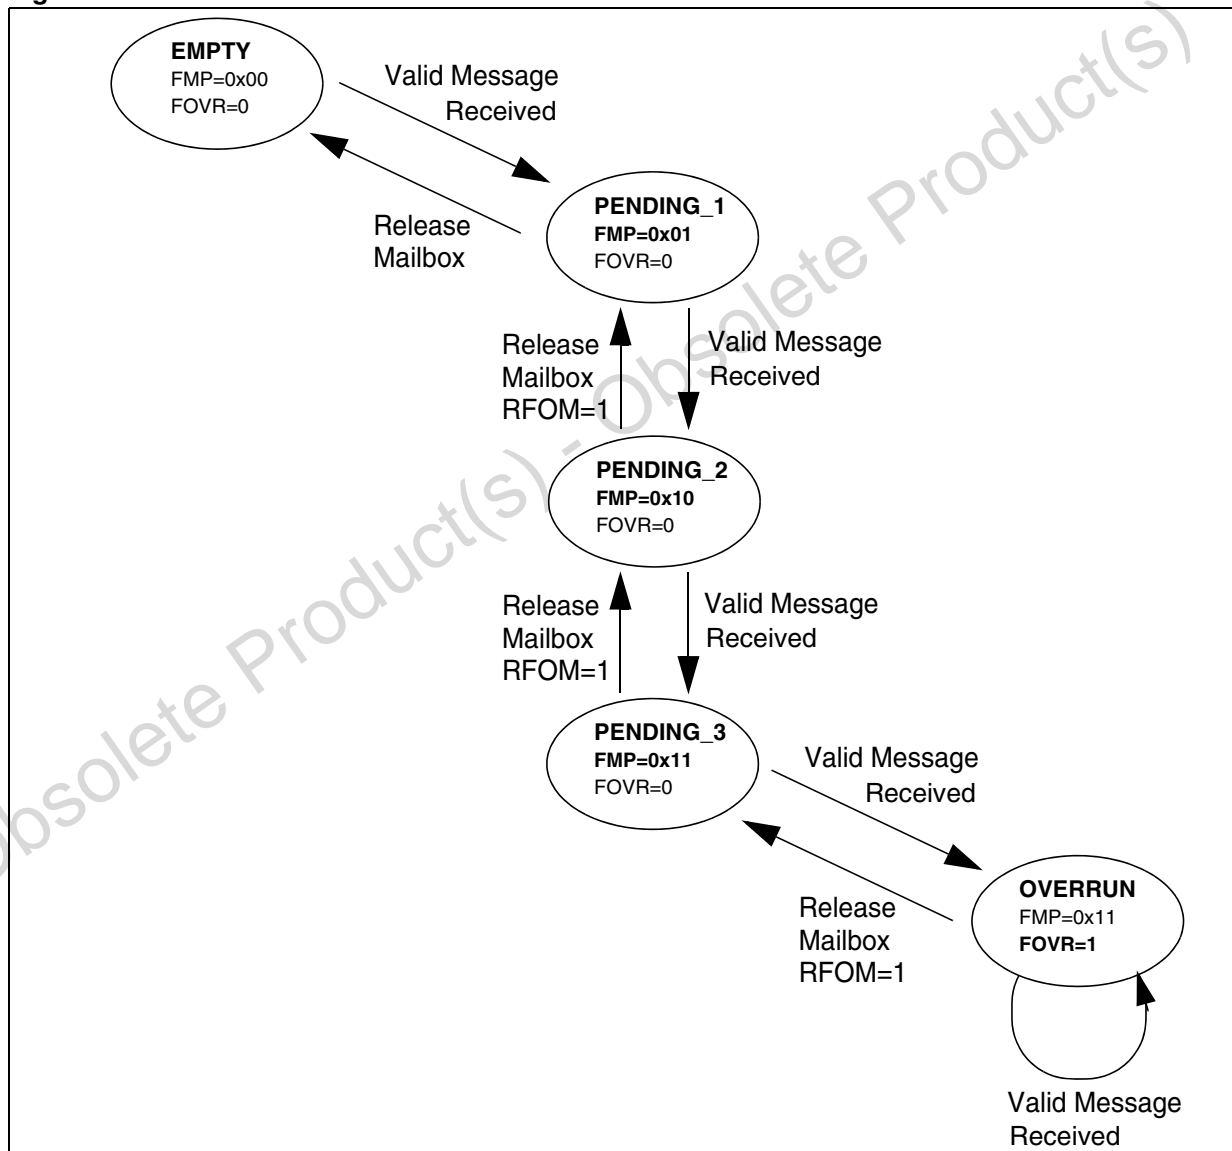

Receiver wakes-up by Address Mark detection when it received a "1" as the most significant bit of a word, thus indicating that the message is an address. The reception of this particular word wakes up the receiver, resets the RWU bit and sets the RDRF bit, which allows the receiver to receive this word normally and to use it as an address word.

**beCAN CONTROLLER (Cont'd)****10.9.4.2 Reception Handling**

For the reception of CAN messages, three mailboxes organized as a FIFO are provided. In order to save CPU load, simplify the software and guarantee data consistency, the FIFO is managed completely by hardware. The application accesses the messages stored in the FIFO through the FIFO output mailbox.

**Valid Message**

A received message is considered as valid **when** it has been received correctly according to the CAN protocol (no error until the last but one bit of the EOF field) **and** It passed through the identifier filtering successfully, see [Section 0.1.4.3 Identifier Filtering](#).

**Figure 101. Receive FIFO states**

**beCAN CONTROLLER (Cont'd)****CAN MASTER STATUS REGISTER (CMSR)**

Reset Value: 0000 0010 (02h)

7							0
0	0	REC	TRAN	WKUI	ERRI	SLAK	INAK

**Note:** To clear a bit of this register the software must write this bit with a one.

Bits 7:4 = Reserved. Forced to 0 by hardware.

Bit 5 = **REC** *Receive*

- Read

The CAN hardware is currently receiver.

Bit 4 = **TRAN** *Transmit*

- Read

The CAN hardware is currently transmitter.

Bit 3 = **WKUI** *Wake-Up Interrupt*

- Read/Clear

This bit is set by hardware to signal that a SOF bit has been detected while the CAN hardware was in sleep mode. Setting this bit generates a status change interrupt if the WKUIE bit in the CIER register is set.

This bit is cleared by software.

Bit 2 = **ERRI** *Error Interrupt*

- Read/Clear

This bit is set by hardware when a bit of the CESR has been set on error detection and the corresponding interrupt in the CEIER is enabled. Setting this bit generates a status change interrupt if the ERRIE bit in the CIER register is set.

This bit is cleared by software.

Bit 1 = **SLAK** *Sleep Acknowledge*

- Read

This bit is set by hardware and indicates to the software that the CAN hardware is now in sleep mode. This bit acknowledges the sleep mode re-

quest from the software (set SLEEP bit in CMCR register).

This bit is cleared by hardware when the CAN hardware has left sleep mode. Sleep mode is left when the SLEEP bit in the CMCR register is cleared. Please refer to the AWUM bit of the CMCR register description for detailed information for clearing SLEEP bit.

Bit 0 = **INAK** *Initialization Acknowledge*

- Read

This bit is set by hardware and indicates to the software that the CAN hardware is now in initialization mode. This bit acknowledges the initialization request from the software (set INRQ bit in CMCR register).

This bit is cleared by hardware when the CAN hardware has left the initialization mode and is now synchronized on the CAN bus. To be synchronized the hardware has to monitor a sequence of 11 consecutive recessive bits on the CAN RX signal.

**CAN TRANSMIT STATUS REGISTER (CTSR)**

Read / Write (

Reset Value: 0000 0000 (00h)

7							0
0	0	TXOK1	TXOK0	0	0	RQCP1	RQCP0

**Note:** To clear a bit of this register the software must write this bit with a one.

Bits 7:6 = Reserved. Forced to 0 by hardware.

Bit 5 = **TXOK1** *Transmission OK for mailbox 1*

- Read

This bit is set by hardware when the transmission request on mailbox 1 has been completed successfully. Please refer to [Figure 7](#).

This bit is cleared by hardware when mailbox 1 is requested for transmission or when the software clears the RQCP1 bit.

## 12 ELECTRICAL CHARACTERISTICS

### 12.1 PARAMETER CONDITIONS

Unless otherwise specified, all voltages are referred to  $V_{SS}$ .

#### 12.1.1 Minimum and Maximum Values

Unless otherwise specified the minimum and maximum values are guaranteed in the worst conditions of ambient temperature, supply voltage and frequencies by tests in production on 100% of the devices with an ambient temperature at  $T_A = 25^\circ\text{C}$  and  $T_A = T_{A\text{max}}$  (given by the selected temperature range).

Data based on characterization results, design simulation and/or technology characteristics are indicated in the table footnotes and are not tested in production. Based on characterization, the minimum and maximum values refer to sample tests and represent the mean value plus or minus three times the standard deviation ( $\text{mean} \pm 3\Sigma$ ).

#### 12.1.2 Typical Values

Unless otherwise specified, typical data is based on  $T_A = 25^\circ\text{C}$ ,  $V_{DD} = 5\text{V}$  (for the  $4.5\text{V} \leq V_{DD} \leq 5.5\text{V}$  voltage range). They are given only as design guidelines and are not tested.

Typical ADC accuracy values are determined by characterization of a batch of samples from a standard diffusion lot over the full temperature range, where 95% of the devices have an error less than or equal to the value indicated ( $\text{mean} \pm 2\Sigma$ ).

#### 12.1.3 Typical Curves

Unless otherwise specified, all typical curves are given only as design guidelines and are not tested.

#### 12.1.4 Loading Capacitor

The loading conditions used for pin parameter measurement are shown in [Figure 117](#).

**Figure 117. Pin Loading Conditions**

#### 12.1.5 Pin Input Voltage

The input voltage measurement on a pin of the device is described in [Figure 118](#).

**Figure 118. Pin input voltage**

## 12.5 CLOCK AND TIMING CHARACTERISTICS

Subject to general operating conditions for  $V_{DD}$ ,  $f_{OSC}$ , and  $T_A$ .

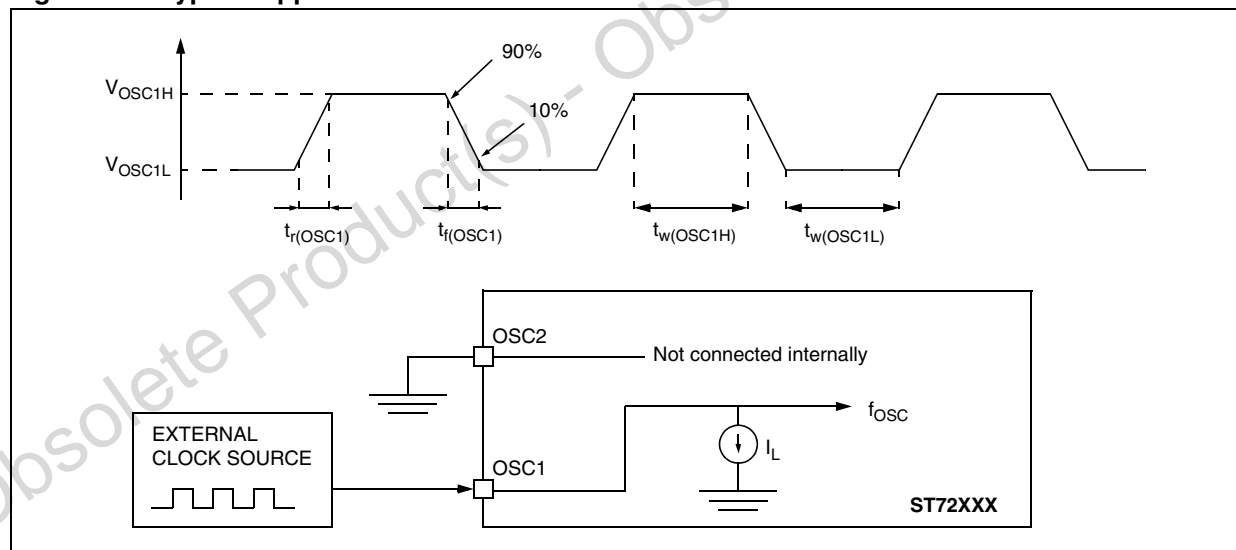

### 12.5.1 General Timings

Symbol	Parameter	Conditions	Min	Typ <sup>1)</sup>	Max	Unit
$t_{c(INST)}$	Instruction cycle time		2	3	12	$t_{CPU}$
		$f_{CPU} = 8 \text{ MHz}$	250	375	1500	ns
$t_{V(IT)}$	Interrupt reaction time <sup>2)</sup> $t_{V(IT)} = \Delta t_{c(INST)} + 10$		10		22	$t_{CPU}$
		$f_{CPU} = 8 \text{ MHz}$	1.25		2.75	$\mu\text{s}$

### 12.5.2 External Clock Source

Symbol	Parameter	Conditions	Min	Typ	Max	Unit
$V_{OSC1H}$	OSC1 input pin high level voltage	see Figure 121	$0.7 \times V_{DD}$		$V_{DD}$	V
$V_{OSC1L}$	OSC1 input pin low level voltage		$V_{SS}$		$0.3 \times V_{DD}$	
$t_{w(OSC1H)}$ $t_{w(OSC1L)}$	OSC1 high or low time <sup>3)</sup>		25			ns
$t_{r(OSC1)}$ $t_{f(OSC1)}$	OSC1 rise or fall time <sup>3)</sup>				5	
$I_L$	OSCx Input leakage current	$V_{SS} \leq V_{IN} \leq V_{DD}$			$\pm 1$	$\mu\text{A}$

Figure 121. Typical Application with an External Clock Source

#### Notes:

1. Data based on typical application software.
2. Time measured between interrupt event and interrupt vector fetch.  $\Delta t_{c(INST)}$  is the number of  $t_{CPU}$  cycles needed to finish the current instruction execution.
3. Data based on design simulation and/or technology characteristics, not tested in production.
