

Welcome to **E-XFL.COM** 

# **Understanding Embedded - DSP (Digital Signal Processors)**

Embedded - DSP (Digital Signal Processors) are specialized microprocessors designed to perform complex mathematical computations on digital signals in real-time. Unlike general-purpose processors, DSPs are optimized for high-speed numeric processing tasks, making them ideal for applications that require efficient and precise manipulation of digital data. These processors are fundamental in converting and processing signals in various forms, including audio, video, and communication signals, ensuring that data is accurately interpreted and utilized in embedded systems.

# Applications of <u>Embedded - DSP (Digital Signal Processors)</u>

#### PIN FUNCTIONS

**External Bus and External Registers.** The following is made to clarify naming conventions used in this specification. The external bus and external registers are "external"

to the DSP core, and are used to access internal and external peripherals.

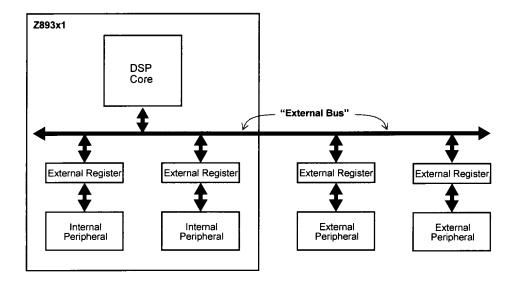

Figure 2. "External" Bus

**EA2–EA0.** External Address Bus (output). These pins control the user-defined register address output (latched). This bus is driven during both internal and external accesses. One of seven user-defined external registers is selected by the processor for reads or writes. External registers EXT0–EXT3 are always available to the user. External registers EXT4–EXT6 are used internally by the processor, or optionally by the user, if the pertinent internal peripherals are disabled. EXT7 is always reserved for use by the processor.

**ED15–ED0.** External Data Bus (input/output). These pins are the data bus for the user-defined external registers. The pins are normally tri-stated, except when these registers are specified as destination registers in a write instruction to an external peripheral. This bus uses the control signals RD/WR, DS, WAIT and the address pins EA2–EA0.

**Note:** The ED Bus was known as the EXT Bus in earlier versions of this document, and may be referred to as the EXT Bus, pins EXT15–EXT0, in other older related documents.

**DS**.Data Strobe (output). This pin provides the data strobe signal for the ED Bus. DS is active for transfers to/from external peripherals only.

**RD/WR.** Read/Write Select (output). This pin controls the data direction signal for the ED Bus. Data is available from the processor on ED15–ED0 when this signal and  $\overline{DS}$  are both Low.

**WAIT.** WAIT State (input). The wait signal is sampled at the rising edge of the clock with appropriate setup and hold times. A single wait-state can be generated internally by setting the appropriate bits in the wait state register. The user must drive this line if multiple wait states are required. This pin has an internal pull-down.

**HALT.** Halt State (input). This pin stops program execution. The processor continuously executes NOPs and the program counter remains at the same value when this pin is held High. This pin has an internal pull-down.

**INTO-INT2.** Interrupts (input, positive edge triggered). These pins control interrupt requests 0–2. Interrupts are generated on the rising edge of the input signal. The DSP

### **PIN FUNCTIONS** (Continued)

fetches the interrupt service routine starting addresses from the following program memory locations:

| Device     | INT0  | INT1  | INT2  |
|------------|-------|-------|-------|
| Z89321/371 | 0FFFH | 0FFEH | 0FFDH |
| Z89391     | FFFFH | FFFEH | FFFDH |

The interrupt priority is INT0 = highest, INT2 = lowest. These pins have internal pull-downs.

**Note:** INT1 and INT2 pins are not available on the 40-pin DIP package.

**CLK Clock (input).** This pin is the clock circuit input.

**RESET.** Reset (input, active Low). This pin resets the processor. It pushes the contents of the Program Counter (PC) onto the stack and then fetches a new PC value from program memory address 0FFCH (or FFFCH for the Z89391) after the RESET signal is released. The Status register is set to all zeros. At power-up, RAM and other registers are undefined; however, they are left unchanged with subsequent

resets. RESET can be asserted asynchronously. If the rising edge of RESET meets prescribed setup conditions relative to the falling edge of the clock, the processor commences execution with a fixed number of clock cycles later. See the Timing Diagrams definitions for details.

**UIO, UI1.** User Input (input). These general-purpose input pins are directly tested by the conditional branch instructions. The pins can also be read as bits in the status register. These are asynchronous input signals that have no special clock synchronization requirements.

**UO0, UO1.** User Output (output). These general-purpose output pins reflect the value of two bits in the status register. These bits may be used to output data by writing to the status register.

**Note:** The value at the output pin is inverted from the value in the register.

The pins SCLK, FS0, FS1, RXD and TXD are described in the CODEC Interface section.

## **AC ELECTRICAL CHARACTERISTICS**

Table 5.  $V_{DD}$  = 5V ±10%,  $T_A$  = 0°C to +70°C for "S" Temperature Range ( $T_A$  = -40°C to +85°C for "E" temperature range, unless otherwise noted)

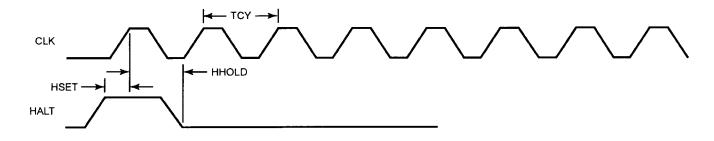

Figure 12. HALT Timing

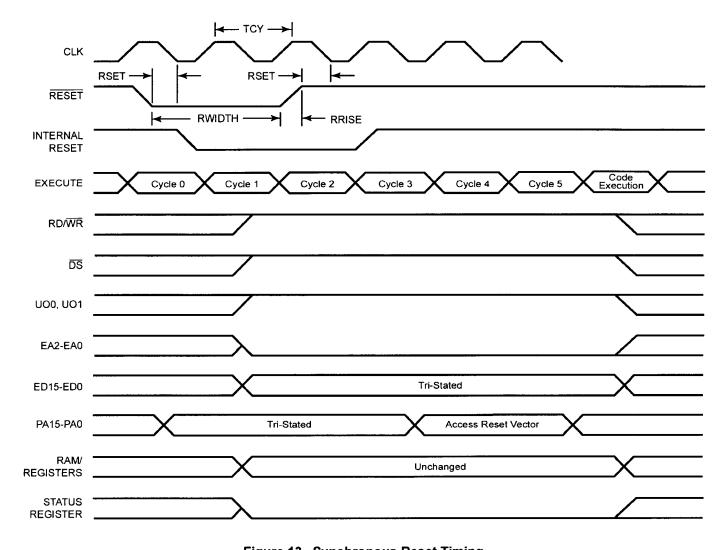

Figure 13. Synchronous Reset Timing

#### **FUNCTIONAL DESCRIPTION**

Instruction Timing. Most instructions are executed in one machine cycle. A multiplication or multiply/accumulate instruction requires a single cycle. Long immediate instructions (and Jump or Call instructions) are executed in two machine cycles. Specific instruction cycle times are described in the Instruction Description section.

Multiply/Accumulate. The multiplier can perform a 16-bit x 16-bit multiply (or multiply/accumulate) in one machine cycle using the Accumulator and/or both the X and Y inputs. The multiplier produces a 32-bit result; however, only the 24 most significant bits are saved for the next instruction or accumulation. For operations on very small numbers, where the least-significant bits are important, the data should first be scaled to avoid truncation errors.

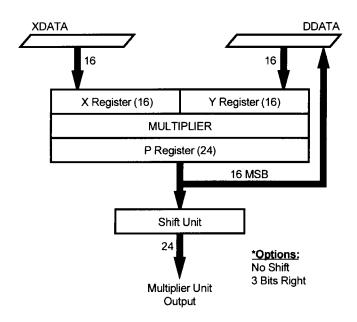

Figure 14. Multiplier Block Diagram

All inputs to the multiplier should be fractional two's-complement, 16-bit binary numbers, putting them in the range [-1 to 0.9999695]. The result is in 24 bits, so the range is [-1 to 0.99999999].

If 8000H is loaded into both the X and Y registers, the multiplication will produce an incorrect result. A positive one (+1) cannot be represented in fractional notation. The multiplier will actually yield the result  $8000H \times 8000H = 8000H$  (-1 x -1 = -1). The user should avoid this case to prevent erroneous results.

A shifter between the P Register and the Multiplier Unit Output can shift the data by three bits right or no shift.

**Data Bus Bank Switch.** There is a switch that connects the X Bus to the DDATA Bus that allows both the X and Y registers to be loaded with the same operand for a one cycle squaring operation. The switch is also used to read the X register.

**ALU.** The ALU has two input ports. One is connected to the output of the 24-bit Accumulator. The other input selects either the Multiplier Unit Output or the 16-bit DDATA bus (left-justified with zeros in the eight LSBs). The ALU performs arithmetic, logic, and shift operations.

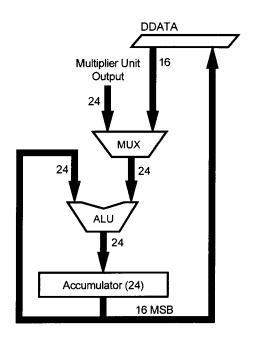

Figure 15. ALU Block Diagram

Hardware Stack. A six-level hardware stack is connected to the DDATA bus to hold subroutine return addresses or data. The Call instruction pushes PC+2 onto the stack, and the RET instruction pops the contents of the stack to the PC.

User Inputs and Outputs. The Z893x1 has two user inputs, UI0 and UI1, and two user outputs, UO0 and UO1. The input pins are connected directly to status register bits S10 and S11. These bits can be read, or they can be used as a condition code in any conditional instruction. The output pins are connected directly to status register bits S5 and S6, and can be written to.

**Note:** The value at the output pin is inverted from the value in the register.

#### REGISTERS

The internal registers are defined in Table 6 below:

**Table 6. Register Definitions** 

| Register | Definition                             |
|----------|----------------------------------------|
| X        | Multiplier X Input, 16-bits            |
| Υ        | Multiplier Y Input, 16-bits            |
| P        | Multiplier Output, 24-bits             |
| A        | Accumulator, 24-bits                   |
| Pn:b     | Six Data RAM Pointers, 8-bits each     |
| PC       | Program Counter, 16-bits               |
| SR       | Status Register, 16-bits               |
| EXT4     | 13-bit Timer Configuration Register    |
| EXT5-1   | CODEC Interface Channel 0 Data         |
| EXT5-2   | CODEC Interface Channel 0 Data         |
| EXT6-1   | CODEC Interface Channel 1 Data         |
| EXT6-2   | CODEC Interface Channel 1 Data         |
| EXT7-1   | CODEC Interface Configuration Register |
| EXT7-2   | Wait-State Generator and CODEC         |
|          | Interface Configuration Register       |

**Note:** The loading and reading of the three pairs of CODEC Interface registers (EXT5-1,2 EXT6-1,2 and EXT7-1,2) are described in the CODEC Interface section.

**X** and **Y** are two 16-bit input registers for the multiplier. These registers can be utilized as temporary registers when the multiplier is not being used.

**P** holds the result of multiplications and is read-only.

A is a 24-bit Accumulator. The output of the ALU is sent to this register. When 16-bit data is transferred into this register, it is placed into the 16 MSBs, and the least significant eight bits are set to zero. Only the upper 16 bits are transferred to the destination register when the Accumulator is selected as a source register in transfer instructions.

**Pn:b** are the pointer registers for accessing data RAM where n = 0, 1, or 2, and b = 0 or 1. These registers can perform either a direct read or write function, and each can point to locations in data RAM.

**PC** is the Program Counter. Any instruction which may modify this register requires two clock cycles.

**SR** is the status register. It contains the ALU status and processor control bits (Table 7).

Table 7. Status Register Bit Functions

| SR Bit      | Function                  | Read/Write |
|-------------|---------------------------|------------|
| S15 (N)     | ALU Negative              | RO         |
| S14 (OV)    | ALU Overflow              | RO         |
| S13 (Z)     | ALU Zero                  | RO         |

| S11 (UI1)   | User Input 1              | RO         |
| S10 (UI0)   | User Input 0              | RO         |
| S9 (SH3)    | MPY Output Arithmetically | R/W        |
|             | Shifted Right by Three    |            |
|             | Bits                      |            |
| S8 (OP)     | Overflow Protection       | R/W        |
| S7 (IE)     | Interrupt Enable          | R/W        |
| S6 (UO1)    | User Output 1             | R/W        |
| S5 (UO0)    | User Output 0             | R/W        |
| S4-S3       | "Short Form Direct" bits  | R/W        |
| S2-S0 (RPL) | RAM Pointer Loop Size     | R/W        |
|             |                           |            |

**Note:** RO = read only, RW = read/write. The status register can always be read in its entirety.

S15–S12 are set/reset by the ALU after an operation.

S11–S10 are set/reset by the user inputs.

If S9 is set, and a multiply/shift option is used, the shifter shifts the result three bits right. This feature allows the data to be scaled and prevents overflows.

If S8 is set, the hardware clamps at maximum positive or negative values instead of overflowing.

S7 enables interrupts.

S6-S0 are control bits.

## **REGISTERS** (Continued)

**Table 8. RPL Description** 

| S2 | S1 | S0 | Loop Size |
|----|----|----|-----------|
| 0  | 0  | 0  | 256       |
| 0  | 0  | 1  | 2         |
| 0  | 1  | 0  | 4         |
| 0  | 1  | 1  | 8         |
| 1  | 0  | 0  | 16        |
| 1  | 0  | 1  | 32        |
| 1  | 1  | 0  | 64        |
| 1  | 1  | 1  | 128       |

The following are not actually registers; however, they have a read/write function that acts primarily the same way as the hardware registers do on the chip:

| Register | Register Definition     |
|----------|-------------------------|
| BUS      | DDATA Bus               |
| Dn:b     | Program Memory Pointers |
| EXTn     | External Registers      |

**BUS** is a read-only register which, when accessed, returns the contents of the D-Bus. BUS is used for emulation only.

**Dn:b** refers to locations in RAM that can be used as a pointer to locations in program memory. These locations make the Z89321/371 capable for coefficient addressing. The programmer decides which location to choose from based on two bits in the status register and two bits in the operand; only the lower 16 possible locations in RAM can be specified. At any one time, there are eight usable pointers, four per bank, and the four pointer are in consecutive locations in RAM. For example, if S3/S4=1 in the status register, then D0:0/D1:0/D2:0/D3:0 refer to register locations 4/5/6/7 in RAM Bank 0.

**Note:** When the data pointers are being written to, a number is actually being loaded to Data RAM. In effect, these data pointers can be used as a limited method for writing to RAM.

**EXT0-EXT3** are used to map external peripherals into the address space of the processor.

**Note:** The actual register RAM does not exist on the chip, but would exist as part of the external device (such as an A/D result latch). The External Address Bus, EA2–EA0, the External Data Bus, ED15–ED0 and the control signals  $\overline{DS}$ , WAIT and RD/ $\overline{WR}$ , are used to access external peripherals.

**EXT4** is used by the 13-bit Timer. If the Timer is disabled, then this address can be used to access an external peripheral on the External Data Bus.

**EXT5** and **EXT6** are used by the CODEC Interface channels 0 and 1 respectively. If a CODEC channel is disabled, the corresponding address can be used to access an external peripheral.

**EXT7** is used to program wait states for EXT0–EXT6, and is not available for accessing an external peripheral.

If both the Timer and CODEC Interface are disabled, there are 7 addresses available to access external peripherals.

If both the Timer and CODEC Interface are enabled, there are 4 addresses available to access external peripherals.

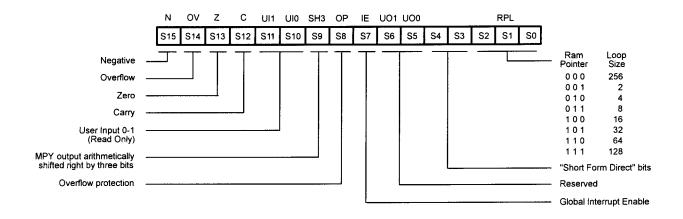

Figure 17. Status Register

#### PERIPHERAL OPERATION

#### Overview

The peripherals for the Z893x1 family consist of a general purpose 13-bit Timer and a dual channel CODEC Interface.

The CODEC Interface contains its own 12-bit Counter/Timer. When the CODEC Interface is disabled, the Counter/Timer is available for general purpose use.

The output of the 12-bit Counter/Timer can also be linked with the input of the 13-bit Timer for extended timing. See the EXT4 and EXT7 register definitions for more information and examples.

### **Enabling and Disabling Peripherals**

At power on, and after a RESET, the 13-bit general purpose Timer is enabled, but count operation is disabled. See the EXT4 register definition for more information concerning the operation of the Timer. While the Timer is enabled, it uses INT2 to signal a time out. When the Timer is disabled, EXT4 and INT2 are available for use by an external peripheral.

At power on, and after a RESET, the CODEC Interface is disabled. See EXT5, EXT6, and EXT7 register definitions for more information concerning the operation of the CODEC Interface. While the CODEC Interface is enabled, it uses INT1 to signal the end of a frame. When a CODEC Interface channel is disabled, its corresponding EXT address is available. When both channels are disabled, EXT5, EXT6, and INT1 are available for use by an external peripheral. EXT7 is always reserved for internal use.

If an internal peripheral is enabled, the External Bus data and data strobe signals for the corresponding register address are not available on the External Bus (internal peripheral data transfers are processed internally).

#### Interrupts

The Z893x1 interrupts are:

INTO General-Purpose Use

INT1 CODEC Interface (when enabled), or else User

INT2 Timer (when enabled), or else User

#### 13-BIT GENERAL PURPOSE TIMER

The General-Purpose Timer can be enabled or disabled. At power-on or RESET, the counter is enabled. When the Timer is disabled, it can only be re-enabled by another RESET. The Timer operates in a continuous or one-shot mode, and can be stopped. The Timer utilizes a 13-bit down-counter.

**Continuous Mode**With a load instruction, the user sets the Timer to run the mode, selects the clock source, and loads a non-zero count value:

- 1. When the down-counter reaches zero, an interrupt is generated on INT2,
- 2. The non-zero count value is automatically reloaded into the down-counter,
- 3. The process continues at step #1.

One-Shot ModeWith a load instruction, the user sets the Timer to run the mode, selects the clock source, and loads a non-zero count value:

- 4. When the down-counter reaches zero, an interrupt is generated on INT2,
- 5. The user interrupt service routine must load a zero value into the Count Operation bit (D14 of EXT4),
- 6. The process stops.

Timing Intervals If the Timer clock source is CLK/2:

Time Interval = (count value) x (2/CLK)

Timer Frequency = (CLK/2) / (count value)

where CLK denotes the system clock frequency.

**Extended Timing Intervals** The Timer interval can be extended beyond 13-bits by using the Timer in conjunction with the CODEC Interface Counter/Timer. The count is thus extended to a maximum of 25 bits:

- 12-bits from the CODEC counter/timer
- 13-bits from the Timer

If the Timer clock source is the CODEC counter output:

Time Interval =(Timer count value) x (CODEC counter/timer period)

Timer Freq. = (CODEC counter/timer freq.) ÷ (Timer count value)

**Timer Interrupt Behavior**The following clarifies the behavior of the Timer interrupt:

- While the Timer is enabled, it utilizes the INT2 service routine address.
- The Timer is enabled after RESET; however, the Timer is in stop mode.
- The INT2 pin has an internal pull-down.
- When the Timer is in run mode, it generates an interrupt each time it counts down to zero.
- When the Timer is disabled, INT2 can be controlled by an external peripheral.

**Note:** If the Timer is to be disabled, and an external peripheral is driving INT2, it should hold INT2 High while the Timer is being disabled.

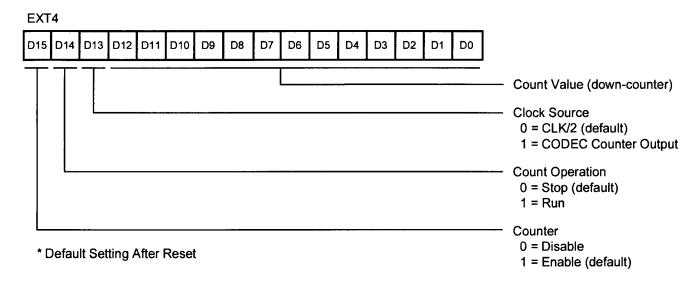

Figure 18. Timer Register EXT4

**FS0**, **FS1**. Frame Sync 0 and Frame Sync 1 (output). These pins are used to mark data transfer/receive frames. The rising and falling edge of the Frame Sync signals indicate the beginning and the end of each serial data transmission.

### **CODEC Interface Interrupt Behavior**

When the transmission of serial data is completed, the CO-DEC Interface generates an internal interrupt which vectors to the INT1 service routine address. This interrupt is coincident with the falling edge of FS1. The following clarifies the behavior of the CODEC Interface interrupt:

- While the CODEC Interface is enabled, it utilizes the INT1 service routine address.
- The CODEC Interface will be disabled after RESET.
- The INT1 pin has an internal pull-down.
- If INT1 is tied High, the CODEC Interface generates an interrupt at the end of each frame transfer.
- If INT1 is not connected, or tied Low, the CODEC Interface not only generates an interrupt when first enabled, but generates an interrupt at the end of each frame transfer.
- When the CODEC Interface is disabled, INT1 can be controlled by an external peripheral.

**Note:** In single channel applications, use Channel 1 because INT1 coincides with FS1, not FS0.

#### Registers

The CODEC Interface registers (EXT5, EXT6 and EXT7) each act as a 2-deep FIFO. See the CODEC Interface Block Diagram for more information, Figure 19. Two operations may be required for some data transfers.

**EXT5** and **EXT6**. The CODEC Interface constantly transfers and receives data during normal operation. The reading of receive data, and the writing of transmit data, are interleaved.

An example of Channel 1 operation in 8 or 16-bit mode, where one can wait for the input data, is as follows:

| LD <dest>, EXT6</dest> | ; Read previous input data from EXT6–1    |
|------------------------|-------------------------------------------|
| LD EVT6 symit datas    |                                           |
| LD EXTO, Simil data>   | ; Push current data from EXT6–2 to EXT6–1 |
|                        | ; Load EXT6–2 with data to be             |
|                        | transmitted                               |

To obtain the input data as soon as it arrives, and extra instruction is required:

| LD EXT6, <anything></anything> | ; Push current input data from EXT6–2 to EXT6–1 |
|--------------------------------|-------------------------------------------------|
| LD <test>, EXT6</test>         | ; Read current input data from EXT6–1           |
| LD EXT6, <xmit data=""></xmit> | ; Load EXT6–2 with data to be transmitted       |

For 64-bit mode, one can use the following code sequence:

| LD <ch. 0="" dest="" input="" msw=""> EXT5</ch.>      | , ; Get MSW of Ch. 0 input                          |
|-------------------------------------------------------|-----------------------------------------------------|
| LD <ch. 1="" dest="" input="" msw=""> EXT6</ch.>      | , ; Get MSW of Ch 1 input                           |
| LD EXT5,<br><ch. 0="" data="" msw="" output=""></ch.> | ; Move LSB of Ch. 0 input<br>and Load MSW of output |
| LD EXT6,<br><ch. 1="" data="" msw="" output=""></ch.> | ; Move LSB of Ch. 1 input<br>and Load MSW of output |
| LD <ch. 0="" input="" lsw="" test="">, EXT5</ch.>     | ; Get LSW of Ch. 0 input                            |
| LD <ch. 1="" input="" lsw="" test="">, EXT6</ch.>     | ; Get LSW of Ch. 1 input                            |
| LD EXT5,<br><ch. 0="" data="" lsw="" output=""></ch.> | ; Load LSW of Ch. 0 output                          |
| LD EXT6,<br><ch. 1="" data="" lsw="" output=""></ch.> | ; Load LSW of Ch. 1 output                          |
|                                                       |                                                     |

Note: EXT# denotes EXT5 or EXT6.

In the 8 and 16-bit modes, EXT5-2 and EXT6-2 are the shift registers for Channel 0 and Channel 1, respectively. In 8-bit mode, the 8-bits reside in the least significant byte for both transmit and receive. In 64-bit mode, the output/input order is EXT 5-1 first, followed by EXT5-2, EXT6-1, and finally by EXT6-2. In all modes, the MSB is shifted out/in first.

Channel 0 uses FS0, EXT5–1, and EXT5–2. Channel 1 uses FS1, EXT6–1, and EXT6–2.

**EXT7.** This register contains the configuration information for the CODEC Interface and the Wait-State Generator. In normal operation, the user writes configuration data for EXT7–1 followed by configuration data for EXT7–2.

Write EXT7 LD EXT7, <config data1>; Move data to 7–2 LD EXT7, <config data2>; Move data to 7–1

#### INSTRUCTION SET

The addressing modes are:

<dregs> This mode is used for access to the lower 16 addresses in each bank of RAM. The 4-bit address comes from 2 bits of the status register and 2 bits of the operand field of the data pointer. Data registers can be used to access data in RAM, but typically these registers are used as pointers to access data from the program memory.

<accind> Similar to the previous mode, the address for the program memory read is stored in the Accumulator. Hence, @A in the second operand field loads the number in memory specified by the address in A.

<direct> The direct mode allows read or write to data RAM from the Accumulator by specifying the absolute address of the RAM in the operand of the instruction. A number between 0 and 255 indicates a location in RAM bank 0, and a number between 256 and 511 indicates a location in RAM bank 1.

This address mode indicates a long immediate operand. A 16-bit word can be loaded directly from the operand into the specified register or memory location.

**simm>** This address mode indicates a short immediate operand. It is used to load 8-bit data into the specified RAM pointer.

<regind> This mode is used for indirect access to the data RAM. The address of the RAM location is stored in the pointer. The "@" symbol indicates "indirect" and precedes the pointer. For example, @P1:1 refers to the location in RAM bank 1 specified by the value in the pointer.

<memind> This mode is used for indirect access to the program memory. The address of the memory is located in a RAM location, which is specified by the value in a pointer. Therefore, @@P1:1 instructs the processor to read from a location in memory. This instruction specifies a value in RAM, and the location of the RAM is, in turn, specified by the value in the pointer.

Note: The data pointer can also be used for a memory access in this manner, but only one "@" precedes the pointer. In both cases, each time the addressing mode is used, the memory address stored in RAM is incremented by one to allow easy transfer of sequential data from program memory.

Bank Switch Operand. The third (optional) operand of the MLD, MPYA and MPYS instructions represents whether the bank switch is set ON or OFF. To more clearly represent this capacity, the keywords ON and OFF are used to state

the status of the switch. These keywords are referenced in the instruction descriptions through the <bank switch> symbol. The most notable capability this item provides is that a source operand can be multiplied by itself (squared).
