What is "Embedded - Microcontrollers"?

"Embedded - Microcontrollers" refer to small, integrated circuits designed to perform specific tasks within larger systems. These microcontrollers are essentially compact computers on a single chip, containing a processor core, memory, and programmable input/output peripherals. They are called "embedded" because they are embedded within electronic devices to control various functions, rather than serving as standalone computers. Microcontrollers are crucial in modern electronics, providing the intelligence and control needed for a wide range of applications.

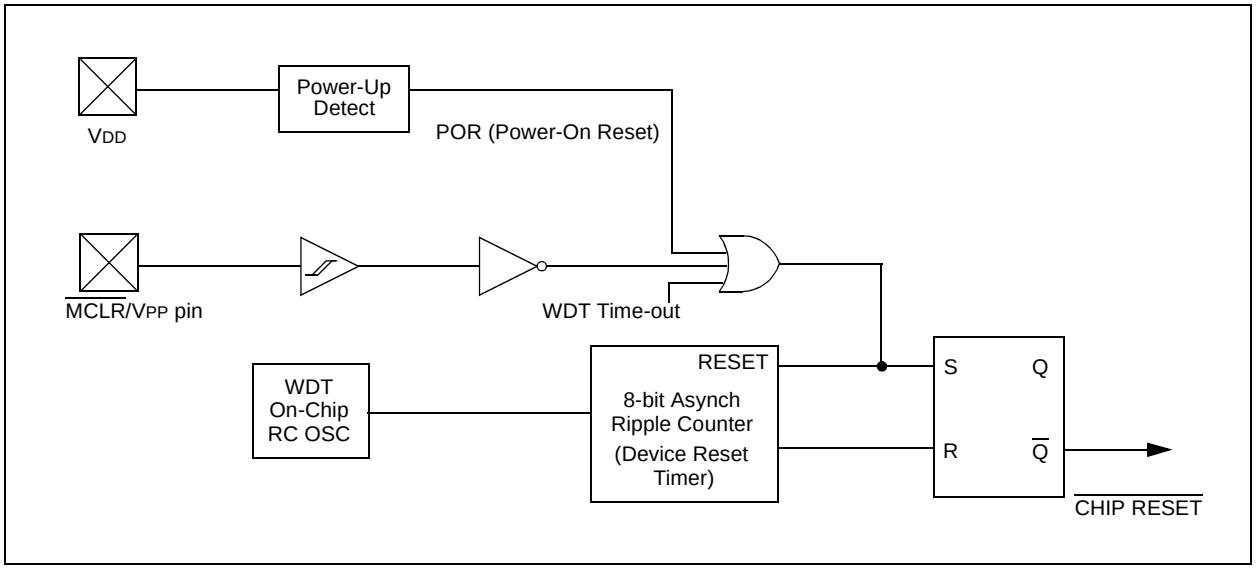
FIGURE 5-1: SIMPLIFIED BLOCK DIAGRAM OF ON-CHIP RESET CIRCUIT



6.5.1 PAGING CONSIDERATIONS – PIC16C56/CR56, PIC16C57/CR57 AND PIC16C58/CR58

If the Program Counter is pointing to the last address of a selected memory page, when it increments it will cause the program to continue in the next higher page. However, the page preselect bits in the STATUS Register will not be updated. Therefore, the next GOTO, CALL or modify PCL instruction will send the program to the page specified by the page preselect bits (PA0 or PA<1:0>).

For example, a NOP at location 1FFh (page 0) increments the PC to 200h (page 1). A GOTO xxx at 200h will return the program to address xxh on page 0 (assuming that PA<1:0> are clear).

To prevent this, the page preselect bits must be updated under program control.

6.5.2 EFFECTS OF RESET

The Program Counter is set upon a RESET, which means that the PC addresses the last location in the last page (i.e., the RESET vector).

The STATUS Register page preselect bits are cleared upon a RESET, which means that page 0 is preselected.

Therefore, upon a RESET, a GOTO instruction at the RESET vector location will automatically cause the program to jump to page 0.

6.6 Stack

PIC16C5X devices have a 10-bit or 11-bit wide, two-level hardware push/pop stack.

A CALL instruction will push the current value of stack 1 into stack 2 and then push the current program counter value, incremented by one, into stack level 1. If more than two sequential CALL's are executed, only the most recent two return addresses are stored.

A RETLW instruction will pop the contents of stack level 1 into the program counter and then copy stack level 2 contents into level 1. If more than two sequential RETLW's are executed, the stack will be filled with the address previously stored in level 2. Note that the W Register will be loaded with the literal value specified in the instruction. This is particularly useful for the implementation of data look-up tables within the program memory.

For the RETLW instruction, the PC is loaded with the Top of Stack (TOS) contents. All of the devices covered in this data sheet have a two-level stack. The stack has the same bit width as the device PC, therefore, paging is not an issue when returning from a subroutine.

6.7 Indirect Data Addressing; INDF and FSR Registers

The INDF Register is not a physical register. Addressing INDF actually addresses the register whose address is contained in the FSR Register (FSR is a *pointer*). This is indirect addressing.

EXAMPLE 6-1: INDIRECT ADDRESSING

- Register file 08 contains the value 10h
- Register file 09 contains the value 0Ah
- Load the value 08 into the FSR Register
- A read of the INDF Register will return the value of 10h
- Increment the value of the FSR Register by one (FSR = 09h)
- A read of the INDF register now will return the value of 0Ah.

Reading INDF itself indirectly (FSR = 0) will produce 00h. Writing to the INDF Register indirectly results in a no-operation (although STATUS bits may be affected).

A simple program to clear RAM locations 10h-1Fh using indirect addressing is shown in Example 6-2.

EXAMPLE 6-2: HOW TO CLEAR RAM USING INDIRECT ADDRESSING

```
            MOVLW   H'10'   ;initialize pointer
            MOVWF   FSR     ; to RAM
NEXT        CLRF    INDF    ;clear INDF Register
            INCF    FSR,F   ;inc pointer
            BTFSC   FSR,4   ;all done?
            GOTO    NEXT    ;NO, clear next
CONTINUE
            :               ;YES, continue
```

The FSR is either a 5-bit (PIC16C54, PIC16CR54, PIC16C55, PIC16C56, PIC16CR56) or 7-bit (PIC16C57, PIC16CR57, PIC16C58, PIC16CR58) wide register. It is used in conjunction with the INDF Register to indirectly address the data memory area.

The FSR<4:0> bits are used to select data memory addresses 00h to 1Fh.

PIC16C54, PIC16CR54, PIC16C55, PIC16C56, PIC16CR56: These do not use banking. FSR<6:5> bits are unimplemented and read as '1's.

PIC16C57, PIC16CR57, PIC16C58, PIC16CR58: FSR<6:5> are the bank select bits and are used to select the bank to be addressed (`00` = bank 0, `01` = bank 1, `10` = bank 2, `11` = bank 3).

* These parameters are characterized but not tested.

† Data in "Typ" column is based on characterization results at 25°C. This data is for design guidance only and is not tested.

Note 1: This is the limit to which VDD can be lowered in SLEEP mode without losing RAM data.

2: The supply current is mainly a function of the operating voltage and frequency. Other factors such as bus loading, oscillator type, bus rate, internal code execution pattern and temperature also have an impact on the current consumption.

a) The test conditions for all IDD measurements in active Operation mode are: OSC1 = external square wave, from rail-to-rail; all I/O pins tristated, pulled to VSS, T0CKI = VDD, $\overline{\text{MCLR}}$ = VDD; WDT enabled/disabled as specified.

b) For standby current measurements, the conditions are the same, except that the device is in SLEEP mode. The power-down current in SLEEP mode does not depend on the oscillator type.

3: Does not include current through REXT. The current through the resistor can be estimated by the formula: IR = VDD/2REXT (mA) with REXT in kΩ.

Voltage on all other pins with respect to V_{SS} ..... –0.6V to (V_{DD} + 0.6V)
Total power dissipation(1) ..... 800 mW
Max. current out of V_{SS} pin ..... 150 mA
Max. current into V_{DD} pin ..... 100 mA
Max. current into an input pin (T0CKI only) ..... ±500 μA
Input clamp current, I_{IK} (V_I < 0 or V_I > V_{DD}) ..... ±20 mA
Output clamp current, I_{OK} (V_O < 0 or V_O > V_{DD}) ..... ±20 mA
Max. output current sunk by any I/O pin ..... 25 mA

Note 1: Power dissipation is calculated as follows: $P_{dis} = V_{DD} \times \{I_{DD} - \sum I_{OH}\} + \sum \{(V_{DD}-V_{OH}) \times I_{OH}\} + \sum(V_{OL} \times I_{OL})$

† NOTICE: Stresses above those listed under "Maximum Ratings" may cause permanent damage to the device. This is a stress rating only and functional operation of the device at those or any other conditions above those indicated in the operation listings of this specification is not implied. Exposure to maximum rating conditions for extended periods may affect device reliability.

18.0 DEVICE CHARACTERIZATION - PIC16LC54A

The graphs and tables provided following this note are a statistical summary based on a limited number of samples and are provided for informational purposes only. The performance characteristics listed herein are not tested or guaranteed. In some graphs or tables, the data presented may be outside the specified operating range (e.g., outside specified power supply range) and therefore outside the warranted range.

"Typical" represents the mean of the distribution at 25°C. "Maximum" or "minimum" represents (mean + 3σ) or (mean – 3σ) respectively, where σ is a standard deviation, over the whole temperature range.

	5.0K	484 kHz	± 14%
	10K	267 kHz	± 15%
	100K	29 kHz	± 19%

The frequencies are measured on DIP packages.

The percentage variation indicated here is part-to-part variation due to normal process distribution. The variation indicated is ±3 standard deviation from average value for VDD = 5V.
