Understanding Embedded - FPGAs (Field Programmable Gate Array)

Embedded - FPGAs, or Field Programmable Gate Arrays, are advanced integrated circuits that offer unparalleled flexibility and performance for digital systems. Unlike traditional fixed-function logic devices, FPGAs can be programmed and reprogrammed to execute a wide array of logical operations, enabling customized functionality tailored to specific applications. This reprogrammability allows developers to iterate designs quickly and implement complex functions without the need for custom hardware.

Applications of Embedded - FPGAs

The versatility of Embedded - FPGAs makes them indispensable in numerous fields. In telecommunications.

PCI Clamp

A programmable PCI clamp is available on the top and bottom banks of the device. The PCI clamp can be turned “ON” or “OFF” on each pin independently. The PCI clamp is used when implementing a 3.3V PCI interface. The

Density Shifting

The LatticeSC family has been designed to ensure that different density devices in the same package have the same pin-out. Furthermore, the architecture ensures a high success rate when performing design migration from lower density parts to higher density parts. In many cases, it is also possible to shift a lower utilization design targeted for a high-density device to a lower density device. However, the exact details of the final resource utilization will impact the likely success in each case.

Signal Descriptions (Cont.)

Signal Name	I/O	Description
D[n:0]	I/O	In parallel configuration modes, D[7:0] receives configuration data, and each pin is pull-up enabled. For slave serial mode, D0 is the data input. D[7:3] is the output internal status for peripheral mode when RDN is low. D[7:0] is also the first byte of MPI data pins. In MPI configuration mode, MPI selectable data bus width from 8 and 16-bit. Driven by a bus master in a write transaction. Driven by MPI in a read transaction.
DP[m:0]	I/O	MPI selectable parity data bus width from 1, 2, and 3-bit DP[0] for D[7:0], DP[1] for D[15:8], and DP[2] for D[23:16].
BUSYN/RCLK/SCK	O	During configuration in peripheral mode, high on BUSYN indicates another byte can be written to the FPGA. If a read operation is done when the device is selected, the same status is also available on D[7] in asynchronous peripheral mode. During configuration in slave parallel mode, low on BUSYN inhibits the external host from sending new data. The output is used by slave parallel and master serial modes only for decompression. During configuration in master parallel and master byte modes, RCLK is a read clock output signal to an external memory. The RCLK frequency is the same as CCLK when used with uncompressed bitstreams. RCLK will be 1/8 the frequency of CCLK when the bitstream is compressed. During configuration in SPI modes, SCK is generated by the device and connected to the CLK input of the FLASH memory.
MPI Interface (Dedicated pin)		
MPI_IRQ_N	O	MPI Interrupt request active low signal is controlled by system bus interrupt controller and may be sourced from any bus error or MPI configuration error. It can be connected to one of MPC860 IRQ pins.
MPI Interface (User I/O if MPI is not used.)		
MPI_CS0N MPI_CS1	I	MPI chip select pins, active low on MPI_CS0N while active high on MPI_CS1. Both have to be active during the whole transfer data phase. During transfer address phase, both can be inactive so that the decoding for them from address can be slow. If they are active during address phase, one cycle can be saved for sync read.
MPI_CLK	I	This is the PowerPC bus clock. It can be a source of the clock for embedded system bus. If MPI_CLK is used as system bus clock, MPI will be set into sync mode by default. All of the operation on PowerPC side of MPI are synchronized to the rising edge of this clock.
MPI_TSIZ[1:0]	I	Driven by a bus master to indicate the data transfer size for the transaction. 01 for byte, 10 for half-word, and 00 for word.
MPI_WR_N	I	Driven high indicates that a read access is in progress. Driven low indicates that a write access is in process.
MPI_BURST	I	Driven active low indicates that a burst transfer is in progress. Driven high indicates that the current transfer is not a burst.
MPI_BDIP	I	Active low “Burst Data in Process” is driven by a PowerPC processor. Asserted indicates that the second beat in front of the current one is requested by the master. Negated before the burst transfer ends to abort the burst data phase.
