### **Understanding Embedded - FPGAs (Field Programmable Gate Array)**

Embedded - FPGAs, or Field Programmable Gate Arrays, are advanced integrated circuits that offer unparalleled flexibility and performance for digital systems. Unlike traditional fixed-function logic devices, FPGAs can be programmed and reprogrammed to execute a wide array of logical operations, enabling customized functionality tailored to specific applications. This reprogrammability allows developers to iterate designs quickly and implement complex functions without the need for custom hardware.

### **Applications of Embedded - FPGAs**

The versatility of Embedded - FPGAs makes them indispensable in numerous fields. In telecommunications,

## PCI Clamp

A programmable PCI clamp is available on the top and bottom banks of the device. The PCI clamp can be turned “ON” or “OFF” on each pin independently. The PCI clamp is used when implementing a 3.3V PCI interface. The

**Single Ended Inputs:** The SC devices support a number of different termination schemes for single ended inputs:

- Parallel to  $V_{CCIO}$  or GND
- Parallel to  $V_{CCIO}/2$
- Parallel to  $V_{TT}$

Figure 2-28 shows the single ended input schemes that are supported. The nominal values of the termination resistors are shown in Table 2-9.

**Figure 2-28. Input Termination Schemes**

Termination Type	Discrete Off-Chip Solution	Lattice On-Chip Solution
Parallel termination to $V_{CCIO}$ , or parallel to GND receiving end		
Parallel termination to $V_{CCIO}/2$ receiving end		
Parallel termination to $V_{TT}$ at receiving end		

In many situations designers can chose whether to use Thevenin or parallel to  $V_{TT}$  termination. The Thevenin approach has the benefit of not requiring a termination voltage to be applied to the device. The parallel to  $V_{TT}$  approach consumes less power.

#### VTT Termination Resources

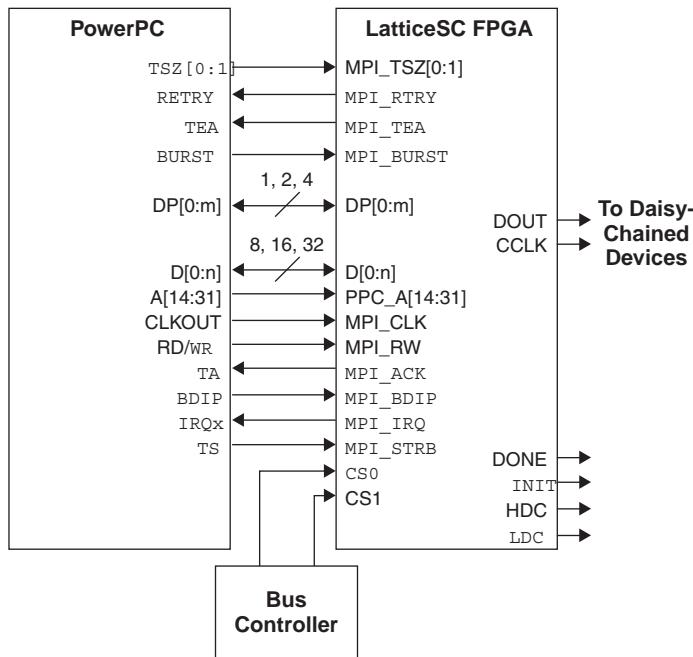

Each I/O bank, except bank 1, has a number of  $V_{TT}$  pins that must be connected if  $V_{TT}$  is used. Note  $V_{TT}$  pins can sink or source current and the power supply they are connected to must be able to handle the relatively high currents associated with the termination circuits. Note:  $V_{TT}$  is not available in all package styles.

On-chip parallel termination to  $V_{TT}$  is supported at the receiving end only. On-chip parallel output termination to  $V_{TT}$  is not supported.

The  $V_{TT}$  internal bus is also connected to the internal  $V_{CMT}$  node. Thus in one bank designers can implement either  $V_{TT}$  termination or  $V_{CMT}$  termination for differential inputs.

#### DDRII/RDRAMII Termination Support

The DDR II memory and RDRAMII (in Bidirection Data mode) standards require that the on-chip termination to  $V_{TT}$  be turned on when a pin is an input and off when the pin is an output. The LatticeSC devices contain the required circuitry to support this behavior. For additional detail refer to technical information at the end of the data sheet.

## Configuration and Testing

The following section describes the configuration and testing features of the LatticeSC family of devices.

### IEEE 1149.1-Compliant Boundary Scan Testability

All LatticeSC devices have boundary scan cells that are accessed through an IEEE 1149.1 compliant test access port (TAP). This allows functional testing of the circuit board, on which the device is mounted, through a serial scan path that can access all critical logic nodes. Internal registers are linked internally, allowing test data to be shifted in and loaded directly onto test nodes, or test data to be captured and shifted out for verification. The test access port consists of dedicated I/Os: TDI, TDO, TCK and TMS. The test access port has its own supply voltage  $V_{CCJ}$  and can operate with LVCMOS33, 25 and 18 standards. For additional detail refer to technical information at the end of the data sheet.

### Device Configuration

All LatticeSC devices contain three possible ports that can be used for device configuration. The serial port, which supports bit-wide configuration, and the sysCONFIG port that supports both byte-wide and serial configuration. The MPI port supports 8-bit, 16-bit or 32-bit configuration.

The serial port supports both the IEEE Std. 1149.1 Boundary Scan specification and the IEEE Std. 1532 In-System Configuration specification. The sysCONFIG port is a 20-pin interface with six of the I/Os used as dedicated pins and the rest being dual-use pins. When sysCONFIG mode is not used, these dual-use pins are available for general purpose I/O. All I/Os for the sysCONFIG and MPI ports are in I/O bank #1.

On power-up, the FPGA SRAM is ready to be configured with the sysCONFIG port active. The IEEE 1149.1 serial mode can be activated any time after power-up by sending the appropriate command through the TAP port. Once a configuration port is selected, that port is locked and another configuration port cannot be activated until the next re-initialization sequence. For additional detail refer to technical information at the end of the data sheet.
