Understanding Embedded - FPGAs (Field Programmable Gate Array)

Embedded - FPGAs, or Field Programmable Gate Arrays, are advanced integrated circuits that offer unparalleled flexibility and performance for digital systems. Unlike traditional fixed-function logic devices, FPGAs can be programmed and reprogrammed to execute a wide array of logical operations, enabling customized functionality tailored to specific applications. This reprogrammability allows developers to iterate designs quickly and implement complex functions without the need for custom hardware.

Applications of Embedded - FPGAs

The versatility of Embedded - FPGAs makes them indispensable in numerous fields. In telecommunications.

Introduction

The LatticeSC family of FPGAs combines a high-performance FPGA fabric, high-speed SERDES, high-performance I/Os and large embedded RAM in a single industry leading architecture. This FPGA family is fabricated in a state of the art technology to provide one of the highest performing FPGAs in the industry.

This family of devices includes features to meet the needs of today's communication network systems. These features include SERDES with embedded advance PCS (Physical Coding sub-layer), up to 7.8 Mbits of sysMEM embedded block RAM, dedicated logic to support system level standards such as RAPIDIO, SPI4.2, SFI-4, UTOPIA, XGMII and CSIX. The devices in this family feature clock multiply, divide and phase shift PLLs, numerous

DLLs and dynamic glitch free clock MUXs which are required in today's high end system designs. High-speed, high-bandwidth I/O make this family ideal for high-throughput systems.

The ispLEVER® design tool from Lattice allows large complex designs to be efficiently implemented using the LatticeSC family of FPGA devices. Synthesis library support for LatticeSC is available for popular logic synthesis tools. The ispLEVER tool uses the synthesis tool output along with the constraints from its floor planning tools to place and route the design in the LatticeSC device. The ispLEVER tool extracts the timing from the routing and back-annotates it into the design for timing verification.

Lattice provides many pre-designed IP (Intellectual Property) ispLeverCORE™ modules for the LatticeSC family. By using these IPs as standardized blocks, designers are free to concentrate on the unique aspects of their design, increasing their productivity.

Innovative high-performance FPGA architecture, high-speed SERDES with PCS support, sysMEM embedded memory and high performance I/O are combined in the LatticeSC to provide excellent performance for today's leading edge systems designs. Table 1-3 details the performance of several common functions implemented within the LatticeSC.

Table1-3. Speed Performance for Typical Functions[1]

Functions	Performance (MHz)[2]
32-bit Address Decoder	539
64-bit Address Decoder	517
32:1 Multiplexer	779
64-bit Adder (ripple)	353
32x8 Distributed Single Port (SP) RAM	768
64-bit Counter (up or down counter, non-loadable)	369
True Dual-Port 1024x18 bits	372
FIFO Port A: x36 bits, B: x9 bits	375

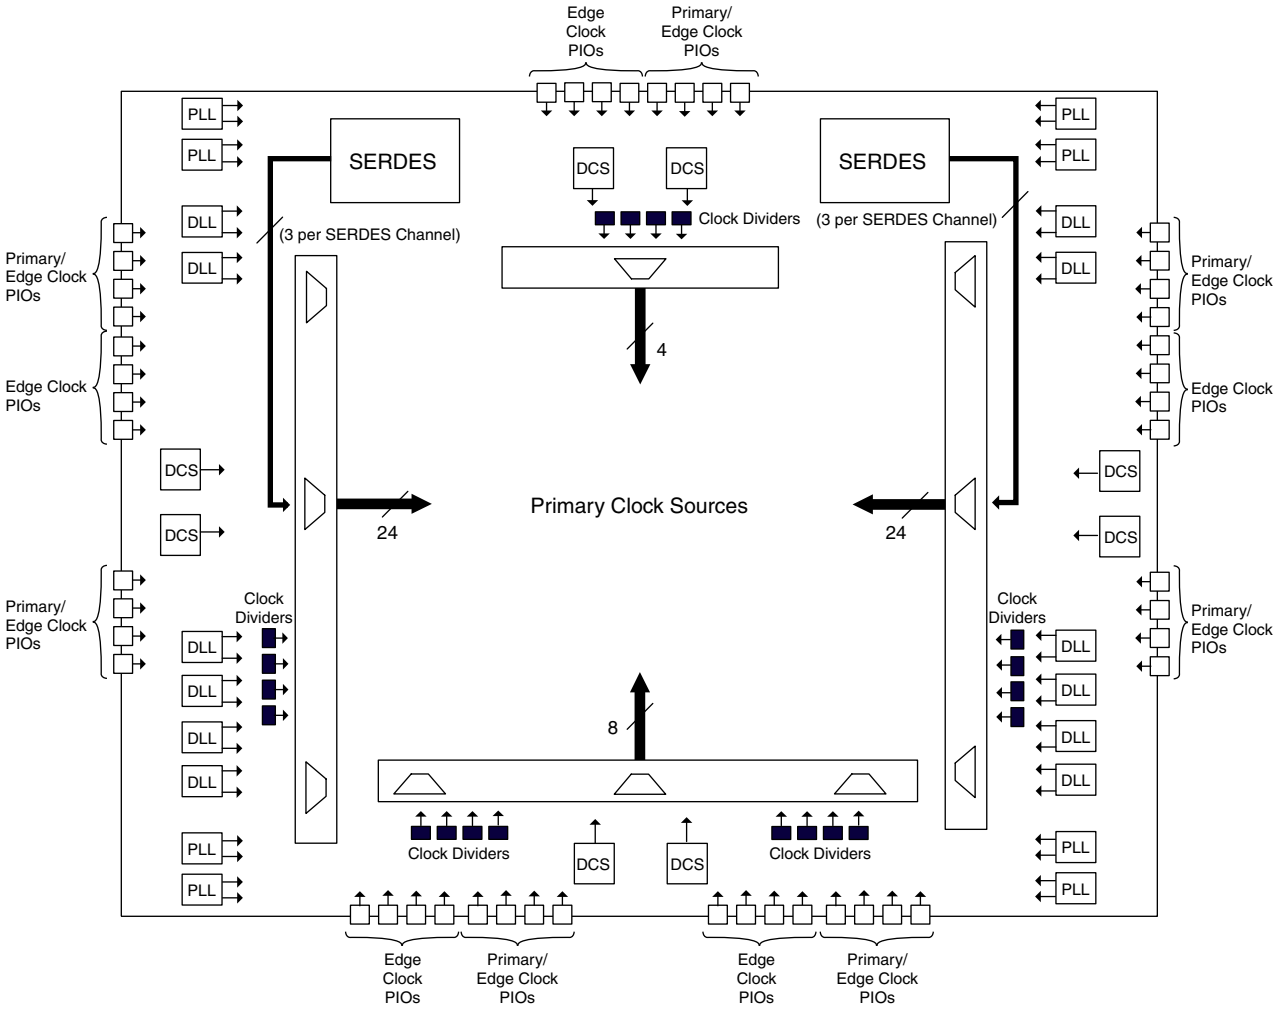
- Two outputs per PLL
- Clock divider outputs
- Digital Clock Select (DCS) block outputs
- Three outputs per SERDES quad

Figure 2-5 shows the arrangement of the primary clock sources.

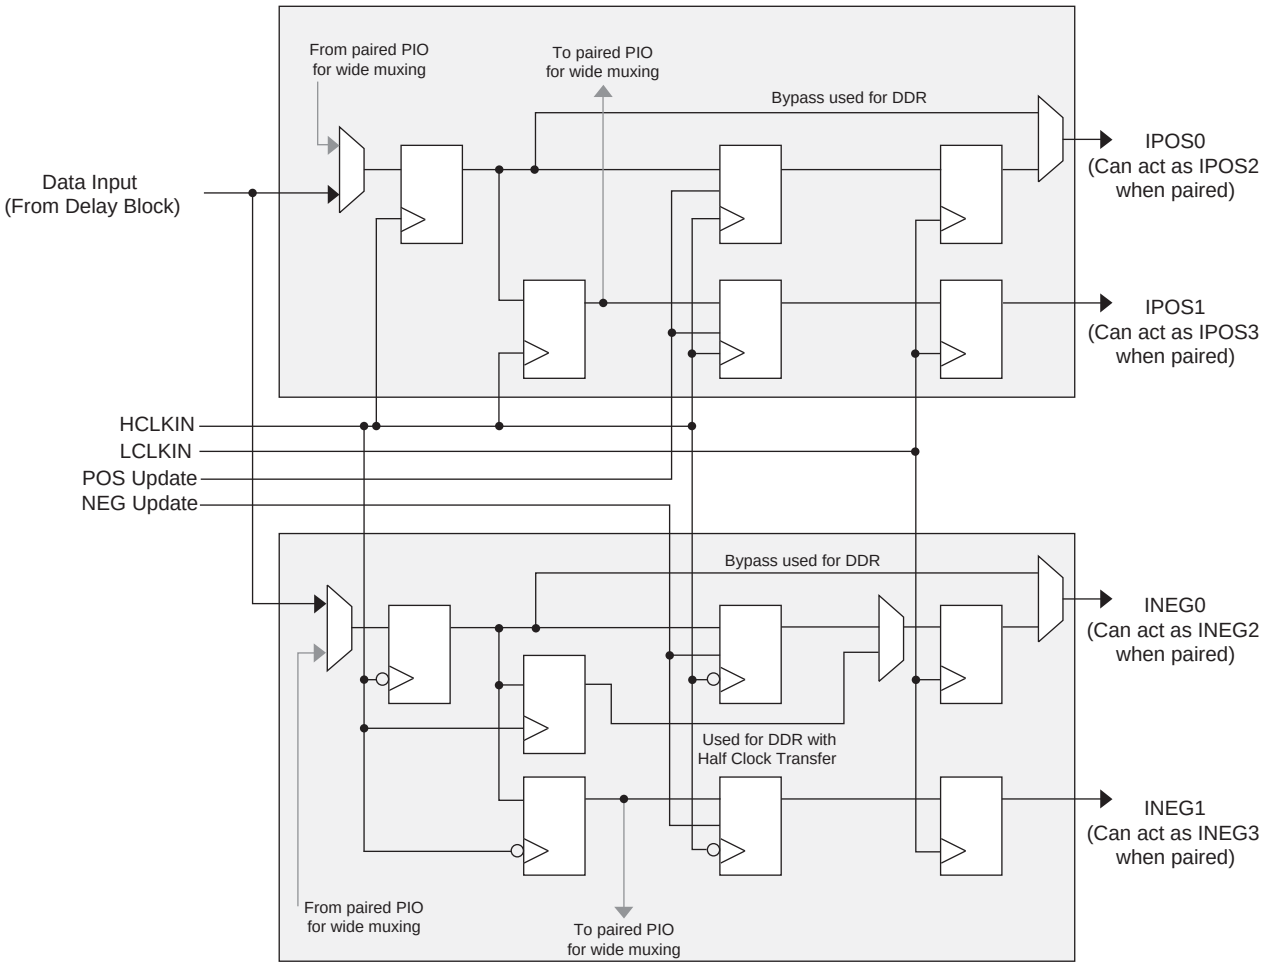
Figure 2-5. Clock Sources



Primary Clock Routing

The clock routing structure in LatticeSC devices consists of 12 Primary Clock lines per quadrant. The primary clocks are generated from 64:1 MUXs located in each quadrant. Three of the inputs to each 64:1 MUX comes from local routing, one is connected to GND and rest of the 60 inputs are from the primary clock sources. Figure 2-6 shows this clock routing.

Figure 2-21. Input DDR/Shift Register Block



Output Register Block

The output register block provides the ability to register signals from the core of the device before they are passed to the PURESPEED I/O buffers. The block contains a register for SDR operation and a group of registers for DDR and shift register operation. The output signal (DO) can be derived directly from one of the inputs (bypass mode), the SDR register or the DDR/shift register block. Figure 2-22 shows the diagram of the Output Register Block.

Output SDR Register/Latch Block

The SDR register operates on the positive edge of the high-speed clock. It has clock enable that is driven by the clock enable output signal generated by the control MUX. In addition it has a variety of programmable options for set/reset including, set or reset, asynchronous or synchronous Local Set Reset LSR (LSR has precedence over CE) and Global Set Reset GSR enable or disable. The register LSR input is driven from LSRO, which is generated from the PIO control MUX. The GSR inputs is driven from the GSR output of the PIO control MUX, which allows the global set-reset to be disabled on a PIO basis.

Output DDR/Shift Block

The DDR/Shift block contains registers and associated logic that support DDR and shift register functions using the high-speed clock and the associated transfer from the low-speed clock domain. It functions as a gearbox allowing low-speed parallel data from the FPGA fabric be output as a higher speed serial stream. Each PIO supports DDR and x2 shift functions. If desired PIOs A and B or C and D can be combined to form x4 shift functions. Figure 2-22 shows a simplified block diagram of the shift register block.
