

Welcome to [E-XFL.COM](https://www.e-xfl.com)

Understanding [Embedded - FPGAs \(Field Programmable Gate Array\)](#)

Embedded - FPGAs, or Field Programmable Gate Arrays, are advanced integrated circuits that offer unparalleled flexibility and performance for digital systems. Unlike traditional fixed-function logic devices, FPGAs can be programmed and reprogrammed to execute a wide array of logical operations, enabling customized functionality tailored to specific applications. This reprogrammability allows developers to iterate designs quickly and implement complex functions without the need for custom hardware.

Applications of Embedded - FPGAs

The versatility of Embedded - FPGAs makes them indispensable in numerous fields. In telecommunications.

Details

Product Status	Obsolete
Number of LABs/CLBs	10000
Number of Logic Elements/Cells	40000
Total RAM Bits	4075520
Number of I/O	562
Number of Gates	-
Voltage - Supply	0.95V ~ 1.26V
Mounting Type	Surface Mount
Operating Temperature	-40°C ~ 105°C (Tj)
Package / Case	1020-BBGA, FCBGA
Supplier Device Package	1020-OFcBGA Rev 2 (33x33)
Purchase URL	https://www.e-xfl.com/product-detail/lattice-semiconductor/lfscm3ga40ep1-6ffan1020i

Architecture Overview

The LatticeSC architecture contains an array of logic blocks surrounded by Programmable I/O Cells (PIC). Interspersed between the rows of logic blocks are rows of sysMEM Embedded Block RAM (EBR). The upper left and upper right corners of the devices contain SERDES blocks and their associated PCS blocks, as shown in Figure 2-1.

Top left and top right corner of the device contain blocks of SERDES. Each block of SERDES contains four channels (quad). Each channel contains a single serializer and de-serializer, synchronization and word alignment logic. The SERDES quad connects with the Physical Coding Sub-layer (PCS) blocks that contain logic to simultaneously perform alignment, coding, de-coding and other functions. The SERDES quad block has separate supply, ground and reference voltage pins.

The PICs contain logic to facilitate the conditioning of signals to and from the I/O before they leave or enter the FPGA fabric. The block provides DDR and shift register capabilities that act as a gearbox between high speed I/O and the FPGA fabric. The blocks also contain programmable Adaptive Input Logic that adjusts the delay applied to signals as they enter the device to optimize setup and hold times and ensure robust performance.

sysMEM EBRs are large dedicated fast memory blocks. They can be configured as RAM, ROM or FIFO. These blocks have dedicated logic to simplify the implementation of FIFOs.

The PFU, PIC and EBR blocks are arranged in a two-dimensional grid with rows and columns as shown in Figure 2-1. These blocks are connected with many vertical and horizontal routing channel resources. The place and route software tool automatically allocates these routing resources.

The corners contain the sysCLOCK Analog Phase Locked Loop (PLL) and Delay Locked Loop (DLL) Blocks. The PLLs have multiply, divide and phase shifting capability; they are used to manage the phase relationship of the clocks. The LatticeSC architecture provides eight analog PLLs per device and 12 DLLs. The DLLs provide a simple delay capability and can also be used to calibrate other delays within the device.

Every device in the family has a JTAG Port with internal Logic Analyzer (ispTRACY) capability. The sysCONFIG™ port which allows for serial or parallel device configuration. The system bus simplifies the connections of the external microprocessor to the device for tasks such as SERDES and PCS configuration or interface to the general FPGA logic. The LatticeSC devices use 1.2V as their core voltage operation with 1.0V operation also possible.

Figure 2-21. Input DDR/Shift Register Block

Output Register Block

The output register block provides the ability to register signals from the core of the device before they are passed to the PURESPEED I/O buffers. The block contains a register for SDR operation and a group of registers for DDR and shift register operation. The output signal (DO) can be derived directly from one of the inputs (bypass mode), the SDR register or the DDR/shift register block. Figure 2-22 shows the diagram of the Output Register Block.

Output SDR Register/Latch Block

The SDR register operates on the positive edge of the high-speed clock. It has clock enable that is driven by the clock enable output signal generated by the control MUX. In addition it has a variety of programmable options for set/reset including, set or reset, asynchronous or synchronous Local Set Reset LSR (LSR has precedence over CE) and Global Set Reset GSR enable or disable. The register LSR input is driven from LSRO, which is generated from the PIO control MUX. The GSR inputs is driven from the GSR output of the PIO control MUX, which allows the global set-reset to be disabled on a PIO basis.

Output DDR/Shift Block

The DDR/Shift block contains registers and associated logic that support DDR and shift register functions using the high-speed clock and the associated transfer from the low-speed clock domain. It functions as a gearbox allowing low-speed parallel data from the FPGA fabric be output as a higher speed serial stream. Each PIO supports DDR and x2 shift functions. If desired PIOs A and B or C and D can be combined to form x4 shift functions. Figure 2-22 shows a simplified block diagram of the shift register block.

Tristate Register Block

The tristate register block provides the ability to register tri-state control signals from the core of the device before they are passed to the PURESPEED I/O buffers. The block contains a register for SDR operation and a group of three registers for DDR and shift register operation. The output signal tri-state control signal (TO) can be derived directly from one of the inputs (bypass mode), the SDR shift register, the DDR registers or the data associated with the buffer (for open drain emulation). Figure 2-24 shows the diagram of the Tristate Register Block.

Tristate SDR Register/Latch Block

The SDR register operates on the positive edge of the high-speed clock. In it has a variety of programmable options for set/reset including, set or reset, asynchronous or synchronous Local Set Reset LSR and Global Set Reset GSR enable or disable. The register LSR input is driven from LSRO, which is generated from the PIO control MUX. The GSR input is driven from the GSR output of the PIO control MUX, which allows the global set-reset to be disabled on a PIO basis.

Tristate DDR/Shift Register Block

The DDR/Shift block is shared with the output block allowing DDR support using the high-speed clock and the associated transfer from the low-speed clock domain. It functions as a gearbox allowing low-speed parallel data from the FPGA fabric to provide a high-speed tri-state control stream.

There is a special mode for DDR-II memory interfaces where the termination is controlled by the output tristate signal. During WRITE cycle when the FPGA is driving the lines, the parallel terminations are turned off. During READ cycle when the FPGA is receiving data, the parallel terminations are turned on.

Figure 2-24. Tristate Register Block¹

I/O Architecture Rules

Table 2-6 shows the PIO usage for x1, x2, x4 gearing. The checkmarks in the columns show the specific PIOs that are used for each gearing mode. When using x2 or x4 gearing, any PIO which is not used for gearing can still be used as an output.

flexiPCS quads are not dedicated solely to industry standard protocols. Each quad (and each channel within a quad) can be programmed for many user defined data manipulation modes. For example, modes governing user-defined word alignment and multi-channel alignment can be programmed for non-standard protocol applications.

For more information on the functions and use of the flexiPCS, refer to the [LatticeSC/M Family flexiPCS Data Sheet](#).

System Bus

Each LatticeSC device connects the FPGA elements with a standardized bus framework referred to as a System Bus. Multiple bus masters optimize system performance by sharing resources between different bus masters such as the MPI and configuration logic. The wide data bus configuration of 32 bits with 4-bit parity supports high-bandwidth, data intensive applications.

There are two types of interfaces on the System Bus, master and slave. A master interface has the ability to perform actions on the bus, such as writes and reads to and from a specific address. A slave interface responds to the actions of a master by accepting data and address on a write and providing data on a read. The System Bus has a memory map which describes each of the slave peripherals that is connected on the bus. Using the addresses listed in the memory map, a master interface can access each of the slave peripherals on the System Bus. Any and all peripherals on the System Bus can be used at the same time. Table 2-12 list all of the available user peripherals on the System Bus after device power-up.

Table 2-12. System Bus User Peripherals

Peripheral	Name	Interface Type
Micro Processor Interface	MPI	Master
User Master Interface	UMI	Master
User Slave Interface	USI	Slave
Serial Management Interface (PLL, DLL, User Logic)	SMI	Slave
Physical Coding Sublayer	PCS	Slave
Direct FPGA Access	DFA	Slave

The peripherals listed in Table 2-12 can be added when the System Bus module is created using Module IP/Manager (ispLEVER Module/IP Manager).

Figure 2-31 also lists the existing peripherals on the System Bus. The gray boxes are available only during configuration. Refer to Lattice technical note TN1080, [LatticeSC sysCONFIG Usage Guide](#), for configuration options. The Status and Config box refers to internal System Bus registers. This document presents all the interfaces listed in Table 2-12 in detail to help the user utilize the desired functions of the System Bus.

Typical Building Block Function Performance

Over Recommended Commercial Operating Conditions at VCC = 1.2V +/- 5%

Pin to Pin Performance (LVCMOS25 12 mA Drive)

Function	-7*	Units
Basic Functions		
32-bit Decoder	6.65	ns
Combinatorial (Pin to LUT to Pin)	5.58	ns
Embedded Memory Functions (Single Port RAM)		
Pin to EBR Input Register Setup (Global Clock)	1.66	ns
EBR Output Clock to Pin (Global Clock)	8.54	ns
Distributed (PFU) RAM (Single Port RAM)		
Pin to PFU RAM Register Setup (Global Clock)	1.32	ns
PFU RAM Clock to Pin (Global Clock)	6.83	ns

*Typical performance per function

Register-to-Register Performance

Function	-7*	Units
Basic Functions		
32-Bit Decoder	539	MHz

Signal Descriptions (Cont.)

Signal Name	I/O	Description
D[n:0]	I/O	In parallel configuration modes, D[7:0] receives configuration data, and each pin is pull-up enabled. For slave serial mode, D0 is the data input. D[7:3] is the output internal status for peripheral mode when RDN is low. D[7:0] is also the first byte of MPI data pins. In MPI configuration mode, MPI selectable data bus width from 8 and 16-bit. Driven by a bus master in a write transaction. Driven by MPI in a read transaction.
DP[m:0]	I/O	MPI selectable parity data bus width from 1, 2, and 3-bit DP[0] for D[7:0], DP[1] for D[15:8], and DP[2] for D[23:16].
BUSYN/RCLK/SCK	O	During configuration in peripheral mode, high on BUSYN indicates another byte can be written to the FPGA. If a read operation is done when the device is selected, the same status is also available on D[7] in asynchronous peripheral mode. During configuration in slave parallel mode, low on BUSYN inhibits the external host from sending new data. The output is used by slave parallel and master serial modes only for decompression. During configuration in master parallel and master byte modes, RCLK is a read clock output signal to an external memory. The RCLK frequency is the same as CCLK when used with uncompressed bit-streams. RCLK will be 1/8 the frequency of CCLK when the bitstream is compressed. During configuration in SPI modes, SCK is generated by the device and connected to the CLK input of the FLASH memory.
MPI Interface (Dedicated pin)		
MPI_IRQ_N	O	MPI Interrupt request active low signal is controlled by system bus interrupt controller and may be sourced from any bus error or MPI configuration error. It can be connected to one of MPC860 IRQ pins.
MPI Interface (User I/O if MPI is not used.)		
MPI_CS0N MPI_CS1	I	MPI chip select pins, active low on MPI_CS0N while active high on MPI_CS1. Both have to be active during the whole transfer data phase. During transfer address phase, both can be inactive so that the decoding for them from address can be slow. If they are active during address phase, one cycle can be saved for sync read.
MPI_CLK	I	This is the PowerPC bus clock. It can be a source of the clock for embedded system bus. If MPI_CLK is used as system bus clock, MPI will be set into sync mode by default. All of the operation on PowerPC side of MPI are synchronized to the rising edge of this clock.
MPI_TSIZE[1:0]	I	Driven by a bus master to indicate the data transfer size for the transaction. 01 for byte, 10 for half-word, and 00 for word.
MPI_WR_N	I	Driven high indicates that a read access is in progress. Driven low indicates that a write access is in process.
MPI_BURST	I	Driven active low indicates that a burst transfer is in progress. Driven high indicates that the current transfer is not a burst.
MPI_BDIP	I	Active low "Burst Data in Process" is driven by a PowerPC processor. Asserted indicates that the second beat in front of the current one is requested by the master. Negated before the burst transfer ends to abort the burst data phase.
