Understanding Embedded - FPGAs (Field Programmable Gate Array)

Embedded - FPGAs, or Field Programmable Gate Arrays, are advanced integrated circuits that offer unparalleled flexibility and performance for digital systems. Unlike traditional fixed-function logic devices, FPGAs can be programmed and reprogrammed to execute a wide array of logical operations, enabling customized functionality tailored to specific applications. This reprogrammability allows developers to iterate designs quickly and implement complex functions without the need for custom hardware.

Applications of Embedded - FPGAs

The versatility of Embedded - FPGAs makes them indispensable in numerous fields. In telecommunications.

Details	
Product Status	Obsolete
Number of LABs/CLBs	10000
Number of Logic Elements/Cells	40000
Total RAM Bits	4075520
Number of I/O	604
Number of Gates	-
Voltage - Supply	0.95V ~ 1.26V
Mounting Type	Surface Mount
Operating Temperature	0°C ~ 85°C (TJ)
Package / Case	1152-BBGA, FCBGA
Supplier Device Package	1152-FCBGA (35x35)

PFU Modes of Operation

Slices can be combined within a PFU to form larger functions. Table 2-4 tabulates these modes and documents the functionality possible at the PFU level.

Routing

There are many resources provided in the LatticeSC devices to route signals individually or as busses with related control signals. The routing resources consist of switching circuitry, buffers and metal interconnect (routing) segments.

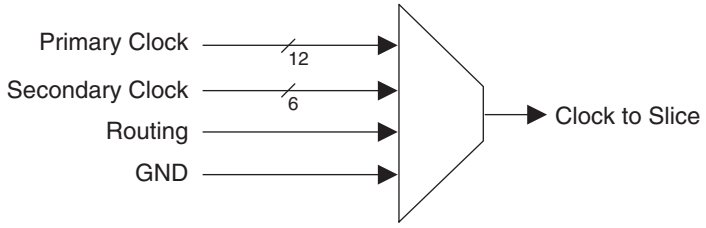
The inter-PFU connections are made with x1 (spans two PFU), x2 (spans three PFU) and x6 (spans seven PFU) resources. The x1 and x2 connections provide fast and efficient connections in horizontal, vertical and diagonal directions. All connections are buffered to ensure high-speed operation even with long high-fanout connections.

The ispLEVER design tool takes the output of the synthesis tool and places and routes the design. Generally, the place and route tool is completely automatic, although an interactive routing editor is available to optimize the design.

sysCLOCK Network

The LatticeSC devices have three distinct clock networks for use in distributing high-performance clocks within the device: primary clocks, secondary clocks and edge clocks. In addition to these dedicated clock networks, users are free to route clocks within the device using the general purpose routing. Figure 2-4 shows the clock resources available to each slice.

Figure 2-4. Slice Clock Selection



Note: GND is available to switch off the network.

Primary Clock Sources

LatticeSC devices have a wide variety of primary clock sources available. Primary clocks sources consists of the following:

- Primary clock input pins
- Edge clock input pins
- Two outputs per DLL

toggled. There are eight DCS blocks per device, located in pairs at the center of each side. Figure 2-9 illustrates the DCS Block diagram.

Figure 2-9. DCS Block Diagram

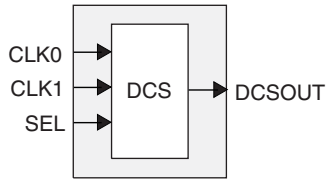


Figure 2-10 shows timing waveforms for one of the DCS operating modes. The DCS block can be programmed to other modes. For more information on the DCS, please see details of additional technical documentation at the end of this data sheet.

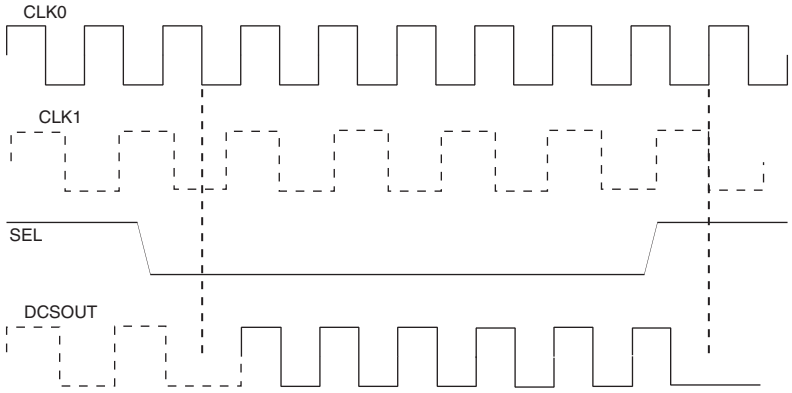
Figure 2-10. DCS Waveforms



Clock Boosting

There are programmable delays available in the clock signal paths in the PFU, PIC and EBR blocks. These allow setup and clock-to-output times to be traded to meet critical timing without slowing the system clock. If this feature is enabled then the design tool automatically uses these delays to improve timing performance.

Global Set/Reset

There is a global set/reset (GSR) network on the device that is distributed to all FFs, PLLs, DLLs and other blocks on the device. This GSR network can operate in two modes:

a) asynchronous - no clock is required to get into or out of the reset state.

b) synchronous - The global GSR net is synchronized to a user selected clock. In this mode it continues to be asynchronous to get into the reset state, but is synchronous to get out of the reset state. This allows all registers on the device to become operational in the same clock period. The synchronous GSR goes out of reset in two cycles from the clock edge where the setup time of the FF was met (not from the GSR being released).

sysCLOCK Phase Locked Loops (PLLs)

The sysCLOCK PLLs provide the ability to synthesize clock frequencies. Each PLL has four dividers associated with it: input clock divider, feedback divider and two clock output dividers. The input divider is used to divide the input clock signal, while the feedback divider is used to multiply the input clock signal.
