Understanding Embedded - FPGAs (Field Programmable Gate Array)

Embedded - FPGAs, or Field Programmable Gate Arrays, are advanced integrated circuits that offer unparalleled flexibility and performance for digital systems. Unlike traditional fixed-function logic devices, FPGAs can be programmed and reprogrammed to execute a wide array of logical operations, enabling customized functionality tailored to specific applications. This reprogrammability allows developers to iterate designs quickly and implement complex functions without the need for custom hardware.

Applications of Embedded - FPGAs

The versatility of Embedded - FPGAs makes them indispensable in numerous fields. In telecommunications,

There is a Digital Control (DCNTL) bus available from the DLL block. This Digital Control bus is available to the delay lines in the PIC blocks in the adjacent banks. The UDDCNTL signal allows the user to latch the current value on the digital control bus.

Figure 2-12 shows the DLL block diagram of the DLL inputs and outputs. The output of the phase frequency detector controls an arithmetic logic unit (ALU) to add or subtract one delay tap. The digital output of this ALU is used to control the delay value of the delay chain and this digital code is transmitted via the DCNTL bus.

The sysCLOCK DLL can be configured at power-up, then, if desired, reconfigured dynamically through the Serial Memory Interface bus which interfaces with the on-chip Microprocessor Interface (MPI) bus. In addition, users can drive the SMI interface from routing if desired.

The user can configure the DLL for many common functions such as clock injection match and single delay cell. Lattice provides primitives in its design for time reference delay (DDR memory) and clock injection delay removal.

Figure 2-12. DLL Diagram

PLL/DLL Cascading

The LatticeSC devices have been designed to allow certain combinations of PLL and DLL cascading. The allowable combinations are as follows:

- PLL to PLL
- PLL to DLL
- DLL to DLL
- DLL to PLL

DLLs are used to shift the clock in relation to the data for source synchronous inputs. PLLs are used for frequency synthesis and clock generation for source synchronous interfaces. Cascading PLL and DLL blocks allows applications to utilize the unique benefits of both DLL and PLLs.

When cascading the DLL to the PLL, the DLL can be used to drive the PLL to create fine phase shifts of an input clock signal. Figure 2-13 shows a shift of all outputs for CLKOP and CLKOS out in time.

1. D refers to open drain capability.

2. User can select either drive current or driver impedances but not both.

3. Emulated with external resistors.

4. No GTL or GTL+ support.

PCI Clamp

A programmable PCI clamp is available on the top and bottom banks of the device. The PCI clamp can be turned “ON” or “OFF” on each pin independently. The PCI clamp is used when implementing a 3.3V PCI interface. The

Initialization and Standby Supply Current

The table below indicates initialization and standby supply current while operating at 85°C junction temperature (T_J), which is the high end of the commercial temperature range, and 105°C, which is the high end of the industrial temperature range. This data assumes all outputs are tri-stated and all inputs are configured as LVCMOS and held at V_{CCIO} or GND. The remaining SERDES supply current for V_{DDIB} and V_{DDOB} is detailed in the SERDES section of this data sheet. For power at your design temperature, it is recommended to use the Power Calculator tool which is accessible in ispLEVER or can be used as a standalone tool. For more information on supply current, see the reference to additional technical documentation available at the end of this data sheet.

Signal Descriptions (Cont.)

Signal Name	I/O	Description
D[n:0]	I/O	<p>In parallel configuration modes, D[7:0] receives configuration data, and each pin is pull-up enabled. For slave serial mode, D0 is the data input.</p> <p>D[7:3] is the output internal status for peripheral mode when RDN is low.</p> <p>D[7:0] is also the first byte of MPI data pins.</p> <p>In MPI configuration mode, MPI selectable data bus width from 8 and 16-bit. Driven by a bus master in a write transaction. Driven by MPI in a read transaction.</p>
DP[m:0]	I/O	MPI selectable parity data bus width from 1, 2, and 3-bit DP[0] for D[7:0], DP[1] for D[15:8], and DP[2] for D[23:16].
BUSYN/RCLK/SCK	O	<p>During configuration in peripheral mode, high on BUSYN indicates another byte can be written to the FPGA. If a read operation is done when the device is selected, the same status is also available on D[7] in asynchronous peripheral mode.</p> <p>During configuration in slave parallel mode, low on BUSYN inhibits the external host from sending new data. The output is used by slave parallel and master serial modes only for decompression.</p> <p>During configuration in master parallel and master byte modes, RCLK is a read clock output signal to an external memory. The RCLK frequency is the same as CCLK when used with uncompressed bitstreams. RCLK will be 1/8 the frequency of CCLK when the bitstream is compressed.</p> <p>During configuration in SPI modes, SCK is generated by the device and connected to the CLK input of the FLASH memory.</p>
MPI Interface (Dedicated pin)		
MPI_IRQ_N	O	MPI Interrupt request active low signal is controlled by system bus interrupt controller and may be sourced from any bus error or MPI configuration error. It can be connected to one of MPC860 IRQ pins.
MPI Interface (User I/O if MPI is not used.)		
MPI_CS0N MPI_CS1	I	MPI chip select pins, active low on MPI_CS0N while active high on MPI_CS1. Both have to be active during the whole transfer data phase. During transfer address phase, both can be inactive so that the decoding for them from address can be slow. If they are active during address phase, one cycle can be saved for sync read.
MPI_CLK	I	This is the PowerPC bus clock. It can be a source of the clock for embedded system bus. If MPI_CLK is used as system bus clock, MPI will be set into sync mode by default. All of the operation on PowerPC side of MPI are synchronized to the rising edge of this clock.
MPI_TSIZ[1:0]	I	Driven by a bus master to indicate the data transfer size for the transaction. 01 for byte, 10 for half-word, and 00 for word.
MPI_WR_N	I	Driven high indicates that a read access is in progress. Driven low indicates that a write access is in process.
MPI_BURST	I	Driven active low indicates that a burst transfer is in progress. Driven high indicates that the current transfer is not a burst.
MPI_BDIP	I	Active low "Burst Data in Process" is driven by a PowerPC processor. Asserted indicates that the second beat in front of the current one is requested by the master. Negated before the burst transfer ends to abort the burst data phase.
