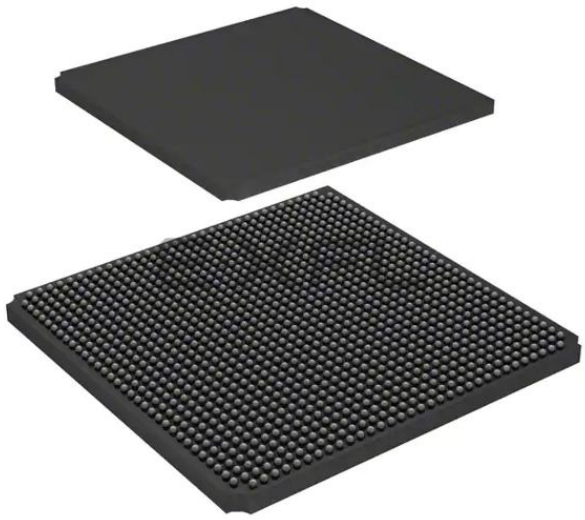
Lattice Semiconductor Corporation - LFSCM3GA80EP1-5FC1152I Datasheet



Welcome to E-XFL.COM

Understanding Embedded - FPGAs (Field Programmable Gate Array)

Embedded - FPGAs, or Field Programmable Gate Arrays, are advanced integrated circuits that offer unparalleled flexibility and performance for digital systems. Unlike traditional fixed-function logic devices, FPGAs can be programmed and reprogrammed to execute a wide array of logical operations, enabling customized functionality tailored to specific applications. This reprogrammability allows developers to iterate designs quickly and implement complex functions without the need for custom hardware.

Applications of Embedded - FPGAs

The versatility of Embedded - FPGAs makes them indispensable in numerous fields. In telecommunications.

Details	
Product Status	Obsolete
Number of LABs/CLBs	20000
Number of Logic Elements/Cells	80000
Total RAM Bits	5816320
Number of I/O	660
Number of Gates	-
Voltage - Supply	0.95V ~ 1.26V
Mounting Type	Surface Mount
Operating Temperature	-40°C ~ 105°C (TJ)
Package / Case	1152-BCBGA, FCBGA
Supplier Device Package	1152-CFCBGA (35x35)
Purchase URL	https://www.e-xfl.com/product-detail/lattice-semiconductor/lfscm3ga80ep1-5fc1152i

DLLs and dynamic glitch free clock MUXs which are required in today's high end system designs. High-speed, high-bandwidth I/O make this family ideal for high-throughput systems.

The ispLEVER® design tool from Lattice allows large complex designs to be efficiently implemented using the LatticeSC family of FPGA devices. Synthesis library support for LatticeSC is available for popular logic synthesis tools. The ispLEVER tool uses the synthesis tool output along with the constraints from its floor planning tools to place and route the design in the LatticeSC device. The ispLEVER tool extracts the timing from the routing and back-annotates it into the design for timing verification.

Lattice provides many pre-designed IP (Intellectual Property) ispLeverCORE™ modules for the LatticeSC family. By using these IPs as standardized blocks, designers are free to concentrate on the unique aspects of their design, increasing their productivity.

Innovative high-performance FPGA architecture, high-speed SERDES with PCS support, sysMEM embedded memory and high performance I/O are combined in the LatticeSC to provide excellent performance for today's leading edge systems designs. Table 1-3 details the performance of several common functions implemented within the LatticeSC.

Table1-3. Speed Performance for Typical Functions[1]

Functions	Performance (MHz)[2]
32-bit Address Decoder	539
64-bit Address Decoder	517
32:1 Multiplexer	779
64-bit Adder (ripple)	353
32x8 Distributed Single Port (SP) RAM	768
64-bit Counter (up or down counter, non-loadable)	369
True Dual-Port 1024x18 bits	372
FIFO Port A: x36 bits, B: x9 bits	375

1. For additional information, see Typical Building BLock Function Performance table in this data sheet.
2. Advance information (-7 speed grade).

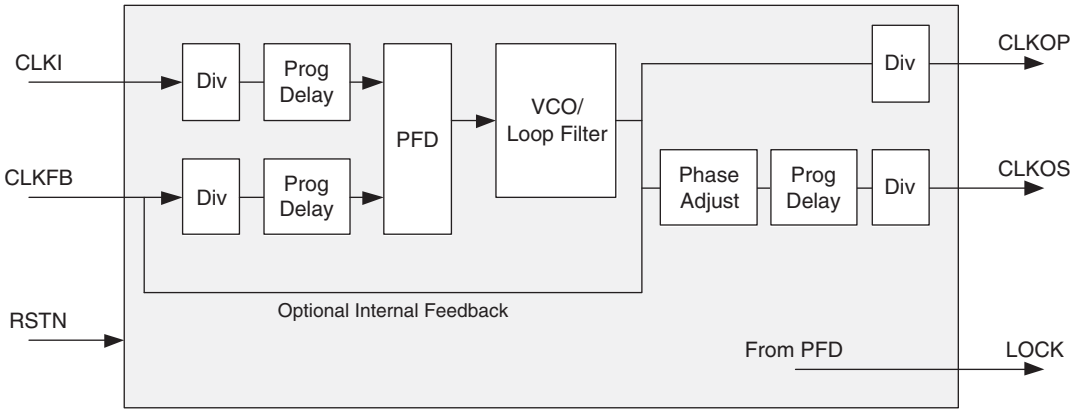
The setup and hold times of the device can be improved by programming a delay in the feedback or input path of the PLL which will advance or delay the output clock with reference to the input clock. This delay can be either programmed during configuration or can be adjusted dynamically.

The Phase Select block can modify the phase of the clock signal if desired. The Spread Spectrum block supports the modulation of the PLL output frequency. This reduces the peak energy in the fundamental and its harmonics providing for lower EMI (Electro Magnetic Interference).

The sysCLOCK PLL can be configured at power-up and then, if desired, reconfigured dynamically through the serial memory interface bus which connects with the on-chip system bus. For example, the user can select inputs, loop filters, divider setting, delay settings and phase shift settings. The user can also directly access the SMI bus through the routing.

The PLL clock input, from pin or routing, feeds into an input divider. There are four sources of feedback signal to the feedback divider: from the clock net, directly from the voltage controlled oscillator (VCO) output, from the routing or from an external pin. The signal from the input clock divider and the feedback divider are passed through the programmable delay before entering the phase frequency detector (PFD) unit. The output of this PFD is used to control the voltage controlled oscillator. There is a PLL_LOCK signal to indicate that VCO has locked on to the input clock signal. Figure 2-11 shows the sysCLOCK PLL diagram.

Figure 2-11. PLL Diagram



For more information on the PLL, please see details of additional technical documentation at the end of this data sheet.

Spread Spectrum Clocking (SSC)

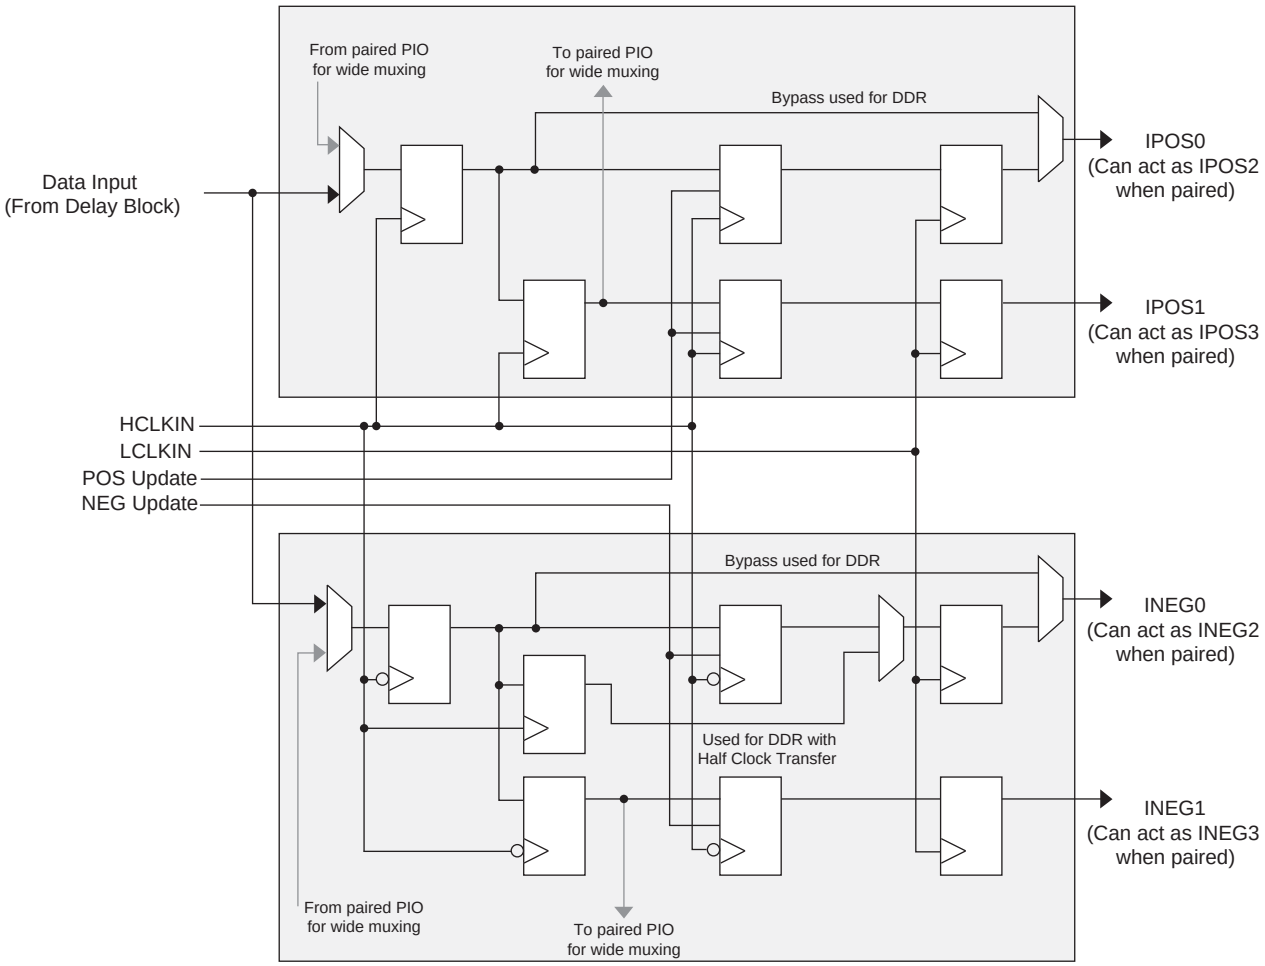
The PLL supports spread spectrum clocking to reduce peak EMI by using “down-spread” modulation. The spread spectrum operation will vary the output frequency (at 30KHz to 500KHz) in a range that is between its nominal value, down to a frequency that is a programmable 1%, 2%, or 3% lower than normal.

Digital Locked Loop (DLLs)

In addition to PLLs, the LatticeSC devices have up to 12 DLLs per device. DLLs assist in the management of clocks and strobes. DLLs are well suited to applications where the clock may be stopped or transferring jitter from input to output is important, for example forward clocked interfaces. PLLs are good for applications requiring the lowest output jitter or jitter filtering. All DLL outputs are routed as primary/edge clock sources.

The DLL has two independent clock outputs, CLKOP and CLKOS. These outputs can individually select one of the outputs from the tapped delay line. The CLKOS has optional fine phase shift and divider blocks to allow this output to be further modified, if required. The fine phase shift block allows the CLKOS output to phase shifted a further 45, 22.5 or 11.25 degrees relative to its normal position. LOCK output signal is asserted when the DLL is locked. The ALU HOLD signal setting allows users to freeze the DLL at its current delay setting.

Figure 2-21. Input DDR/Shift Register Block



Output Register Block

The output register block provides the ability to register signals from the core of the device before they are passed to the PURESPEED I/O buffers. The block contains a register for SDR operation and a group of registers for DDR and shift register operation. The output signal (DO) can be derived directly from one of the inputs (bypass mode), the SDR register or the DDR/shift register block. Figure 2-22 shows the diagram of the Output Register Block.

Output SDR Register/Latch Block

The SDR register operates on the positive edge of the high-speed clock. It has clock enable that is driven by the clock enable output signal generated by the control MUX. In addition it has a variety of programmable options for set/reset including, set or reset, asynchronous or synchronous Local Set Reset LSR (LSR has precedence over CE) and Global Set Reset GSR enable or disable. The register LSR input is driven from LSRO, which is generated from the PIO control MUX. The GSR inputs is driven from the GSR output of the PIO control MUX, which allows the global set-reset to be disabled on a PIO basis.

Output DDR/Shift Block

The DDR/Shift block contains registers and associated logic that support DDR and shift register functions using the high-speed clock and the associated transfer from the low-speed clock domain. It functions as a gearbox allowing low-speed parallel data from the FPGA fabric be output as a higher speed serial stream. Each PIO supports DDR and x2 shift functions. If desired PIOs A and B or C and D can be combined to form x4 shift functions. Figure 2-22 shows a simplified block diagram of the shift register block.

Single Ended Inputs: The SC devices support a number of different termination schemes for single ended inputs:

- Parallel to V_{CCIO} or GND
- Parallel to $V_{CCIO}/2$
- Parallel to V_{TT}

Figure 2-28 shows the single ended input schemes that are supported. The nominal values of the termination resistors are shown in Table 2-9.

Figure 2-28. Input Termination Schemes

Termination Type	Discrete Off-Chip Solution	Lattice On-Chip Solution
Parallel termination to to V_{CCIO}, or parallel to GND receiving end		Parallel termination to $V_{CCIO}/2$ receiving end		Parallel termination to V_{TT} at receiving end		
In many situations designers can chose whether to use Thevenin or parallel to V_{TT} termination. The Thevenin approach has the benefit of not requiring a termination voltage to be applied to the device. The parallel to V_{TT} approach consumes less power.

VTT Termination Resources

Each I/O bank, except bank 1, has a number of V_{TT} pins that must be connected if V_{TT} is used. Note V_{TT} pins can sink or source current and the power supply they are connected to must be able to handle the relatively high currents associated with the termination circuits. Note: V_{TT} is not available in all package styles.

On-chip parallel termination to V_{TT} is supported at the receiving end only. On-chip parallel output termination to V_{TT} is not supported.

The V_{TT} internal bus is also connected to the internal V_{CMT} node. Thus in one bank designers can implement either V_{TT} termination or V_{CMT} termination for differential inputs.

DDRII/RLDRAMII Termination Support

The DDR II memory and RLDRAMII (in Bidirection Data mode) standards require that the on-chip termination to V_{TT} be turned on when a pin is an input and off when the pin is an output. The LatticeSC devices contain the required circuitry to support this behavior. For additional detail refer to technical information at the end of the data sheet.
