#### Understanding Embedded - Microprocessors

Embedded microprocessors are specialized computing chips designed to perform specific tasks within an embedded system. Unlike general-purpose microprocessors found in personal computers, embedded microprocessors are tailored for dedicated functions within larger systems, offering optimized performance, efficiency, and reliability. These microprocessors are integral to the operation of countless electronic devices, providing the computational power necessary for controlling processes, handling data, and managing communications.

#### Applications of **Embedded - Microprocessors**

<sup>1</sup> The difference between  $V_{DDL}$  and  $V_{DDSYN}$  cannot be more than 100 mV.

### 7 Thermal Calculation and Measurement

For the following discussions,  $P_D = (V_{DDL} \times I_{DDL}) + P_{I/O}$ , where  $P_{I/O}$  is the power dissipation of the I/O drivers.

### NOTE

The V<sub>DDSYN</sub> power dissipation is negligible.

### 7.1 Estimation with Junction-to-Ambient Thermal Resistance

An estimation of the chip junction temperature, T<sub>J</sub>, in °C can be obtained from the following equation:

$$T_{J} = T_{A} + (R_{\theta JA} \times P_{D})$$

where:

 $T_A$  = ambient temperature (°C)

 $R_{\theta JA}$  = package junction-to-ambient thermal resistance (°C/W)

 $P_D$  = power dissipation in package

The junction-to-ambient thermal resistance is an industry standard value that provides a quick and easy estimation of thermal performance. However, the answer is only an estimate; test cases have demonstrated that errors of a factor of two (in the quantity  $T_I - T_A$ ) are possible.

The IRQ lines are synchronized internally and do not have to be asserted or negated with reference to the CLKOUT. The I41, I42, and I43 timings are specified to allow correct functioning of the IRQ lines detection circuitry and have no direct relation with the total system interrupt latency that the MPC875/MPC870 is able to support.
